

Existence of Non-Contractible Periodic Orbits for Homeomorphisms of the Open Annulus

JONATHAN CONEJEROS AND FÁBIO ARMANDO TAL*

Abstract

In this article we consider homeomorphisms of the open annulus $\mathbb{A} = \mathbb{T}^1 \times \mathbb{R}$ which are isotopic to the identity and preserve a Borel probability measure of full support, focusing on the existence of non-contractible periodic orbits. Assume f such homeomorphism such that the connected components of the set of fixed points of f are all compact. Further assume that there exists \tilde{f} a lift of f to the universal covering of \mathbb{A} such that the set of fixed points of \tilde{f} is non-empty and that this set projects into an open topological disk of \mathbb{A} . We prove that, in this setting, one of the following two conditions must be satisfied: (1) f has non-contractible periodic points of arbitrarily large prime period, or (2) for every compact set K of \mathbb{A} there exists a constant M (depending on the compact set) such that, if \tilde{z} and $\tilde{f}^n(\tilde{z})$ project on K , then their projections on the first coordinate have distance less or equal to M . Some consequence for homeomorphisms of the open annulus whose rotation set is reduced to an integer number are derived.

1 Introduction

H. Poincaré's rotation number concept for circle homeomorphisms is one of the most celebrated and useful tools in dynamical systems theory, one that is familiar to almost all students and researchers in the field. Such success has lead to the generalization of the idea to several different contexts, where they have developed into important and useful tools. One of the first such generalizations was the concept of rotation interval for endomorphisms of the circle, see [NPT]. Given a continuous degree one map $f : \mathbb{T}^1 \rightarrow \mathbb{T}^1$ and a lift $\tilde{f} : \mathbb{R} \rightarrow \mathbb{R}$, one can define the rotation interval of \tilde{f} as follows:

$$\rho(\tilde{f}) := \left\{ \rho \mid \exists \tilde{z} \in \mathbb{R}, \lim_{n \rightarrow +\infty} \frac{1}{n} (\tilde{f}^n(\tilde{z}) - \tilde{z}) = \rho \right\}.$$

As is the case of circle homeomorphisms, it is possible to show that f has periodic points if and only if the rotation interval of \tilde{f} contains a rational point

*The first author was supported by CNPq-Brasil. The second author was partially supported by FAPESP, CNPq-Brasil and CAPES.

and moreover, if $p/q \in \rho(\check{f})$, then there exists some q periodic point z with rotation number p/q , that is, there exists \check{z} lifting z such that $\check{f}^q(\check{z}) = \check{z} + p$. Not only that, it can be shown that $\rho(\check{f})$ is always a closed interval and that \check{f} also presents *uniformly bounded deviations* from its rotation set, that is, there exists a positive constant M such that, for all $\check{z} \in \mathbb{R}, n \in \mathbb{Z}$, it holds that $d(\check{f}^n(\check{z}) - \check{z}, n\rho(\check{f})) < M$. In particular, there exists a dichotomy between two different phenomena: A circle endomorphisms can either have uniformly bounded deviations from a rigid rotation, or it must have sequence of periodic points with arbitrarily large prime period and distinct rotation numbers.

As expected, there have been a large effort in trying to generalize the concept of rotation number for dynamical systems in dimension higher than one, trying to get suitable extensions of the 1-dimensional results. But this task is not that simple, even for dimension 2, where the best attempts are only suitable for homeomorphisms in the homotopy class of the identity. The best known case here is the notion of rotation set of a torus homeomorphism, as introduced by M. Misiurewicz and K. Ziemian in [MZ]. Given a homeomorphism $f : \mathbb{T}^2 \rightarrow \mathbb{T}^2$ homotopic to the identity, and a lift $\check{f} : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ to its universal covering space and $\pi : \mathbb{R}^2 \rightarrow \mathbb{T}^2$ the covering projection, one can define the rotation set of \check{f} as follows:

$$\rho(\check{f}) := \left\{ v \mid \exists (n_k)_{k \in \mathbb{N}} \in \mathbb{N}, \exists (\check{z}_k)_{k \in \mathbb{N}} \in \mathbb{R}^2, \lim_{k \rightarrow +\infty} \frac{1}{n_k} (\check{f}^{n_k}(\check{z}_k) - \check{z}_k) = v \right\}.$$

Elements in $\rho(\check{f})$ are called *rotation vectors* for \check{f} . Furthermore, if a point $z \in \mathbb{T}^2$ is such that for some $\check{z} \in \pi^{-1}(z)$, the limit $\lim_{n \rightarrow +\infty} \frac{\check{f}^n(\check{z}) - \check{z}}{n} = v$ exists, then v is called the *rotation vector of z* .

The use of rotation sets as a tool for understanding and describing dynamical behavior in surfaces started in the 90s (see [F1], [F2], [MZ] and [LIM]), and has developed in a very active field in the last decade, with some significant contributions (see [BCH], [KT1]). Lately, a couple of aspects of the subject have been drawing some increased attention. First, there have been several studies trying to determine how well does the rotation set capture the possible non-linear displacements. More specifically, under what conditions should one expect to get uniformly bounded deviations from the rotation set. To be precise, in the case where f is a homeomorphism of the 2-torus homotopic to the identity, and \check{f} is a lift to the universal covering, when does it hold that there exists a positive constant M such that, for all $\check{z} \in \mathbb{R}^2, n \in \mathbb{N}$, it holds that $d(\check{f}^n(\check{z}) - \check{z}, n\rho(\check{f})) < M$, as in the case of circle endomorphisms? It is known that this is not the case when the rotation set of f is a singleton (see [KoK], [KT2]), even for area-preserving maps. On the other hand bounded deviations are present when the rotation set of f has non-empty interior (see [D], [A-Z] and [LecT]). There has also been a large number of results with a similar flavor when the rotation set of f is a non-degenerate line-segment, see for instance [D], [Ko] and [KPS].

A second direction, one that has drawn a particular interest due to connections to similar problems in symplectic dynamics, is to describe sufficient conditions for the existence of periodic points with distinct rotation numbers.

Whenever f is a homeomorphism of a manifold M in the isotopy class of the identity and \tilde{f} is a lift to the universal covering space \tilde{M} commuting with the covering transformations, and $\tilde{\pi} : \tilde{M} \rightarrow M$ is the covering map, we say that $z \in M$ is a *contractible periodic point* if every $\tilde{z} \in \tilde{\pi}^{-1}(z)$ is also periodic, otherwise we call z a *non-contractible periodic point*. The question on whether a homeomorphism of the two-dimensional torus has periodic points with distinct rotation numbers is often reduced to the study of the co-existence of *contractible* and *non-contractible* periodic points, and recent works concerning conditions for the existence of non-contractible periodic points in surface or symplectic dynamics can be found in [G], [GG] and [T].

In this work we study how much of the bounded deviation machinery applies to the case of conservative map on a non-compact surface. Our main goal is to examine how far the dichotomy that was present in the study of endomorphisms of the circle holds in the case of the open annulus $\mathbb{A} := \mathbb{T}^1 \times \mathbb{R}$. We will denote by $\tilde{\pi} : \tilde{\mathbb{A}} := \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{A}$ the universal covering map of \mathbb{A} . Our main result is the following.

Theorem A. *Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure of full support. Assume that the connected components of the set of fixed points of f are all compact. Let \tilde{f} be a lift of f to $\tilde{\mathbb{A}} := \mathbb{R} \times \mathbb{R}$. Assume that \tilde{f} has fixed points and that there exists an open topological disk $U \subset \mathbb{A}$ such that the set of fixed points of \tilde{f} projects into U . Then*

- (1) *either there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in (0, 1/q]$, the map $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) + (r, 0)$ or $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) - (r, 0)$ has a fixed point. In particular, f has non-contractible periodic points of arbitrarily large prime period;*
- (2) *or for every compact set K of \mathbb{A} , there exists a real constant $M > 0$ such that, for every point \tilde{z} and every integer $n \geq 1$ such that \tilde{z} and $\tilde{f}^n(\tilde{z})$ belong to $\tilde{\pi}^{-1}(K)$, one has*

$$|p_1(\tilde{f}^n(\tilde{z})) - p_1(\tilde{z})| \leq M,$$

where $p_1 : \tilde{\mathbb{A}} \rightarrow \mathbb{R}$ is the projection on the first coordinate.

In order to prove Theorem A, we prove a recurrence type theorem in the lifted dynamics of a homeomorphism of \mathbb{A} that is isotopic to the identity.

Theorem B. *Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure of full support. Let \tilde{f} be a lift of f to $\tilde{\mathbb{A}}$. Suppose that \tilde{f} has fixed points. Then*

- (1) *either there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in (0, 1/q]$, the map $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) + (r, 0)$ or $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) - (r, 0)$ has a fixed point;*

- (2) or for every recurrent point $z \in \mathbb{A}$, there exists an open topological disk $V \subset \mathbb{A}$ containing z such that: if \tilde{V} is a lift of V and \tilde{z} is the lift of z contained in \tilde{V} , then for every integer n satisfying $f^n(z) \in V$ we have $\tilde{f}^n(\tilde{z}) \in \tilde{V}$.

Theorem B has an interesting consequence, which we describe below. In the next section, given f a homeomorphism of the open annulus \mathbb{A} in the isotopy class of the identity, and a lift \tilde{f} to $\tilde{\mathbb{A}}$, we will properly define the rotation set of \tilde{f} , $\text{Rot}(\tilde{f})$, but it is a similar concept to the rotation set of a torus homeomorphism. Let us call such a homeomorphism *irrotational* if its rotation set is reduced to an integer number. In this case, f has a lift \tilde{f} to $\tilde{\mathbb{A}}$ satisfying $\text{Rot}(\tilde{f}) = \{0\}$, which we call the *irrotational lift* of f . An immediate consequence of the previous theorem is the following.

Theorem C. *Let f be an irrotational homeomorphism of \mathbb{A} which preserves a Borel probability measure of full support. Let \tilde{f} be the irrotational lift of f . Then the set of bi-recurrent points of \tilde{f} is dense in $\tilde{\mathbb{A}}$. In particular \tilde{f} is non-wandering.*

Theorem C is a good example of the difficulties present when working on the open annulus. The stated result, for the case where f is a homeomorphism of the closed annulus is a well-known consequence of Atkinson's Lemma in the field (see [A]). But the proof for the closed annulus uses the fact that for irrotational homeomorphisms of the closed annulus, every invariant Borel probability measure has an associated *measure rotation number* which is null. This simple fact does not hold in the non-compact setting.

The main technique used in the proofs of Theorems A and B is the Equivariant Brouwer Theory of P. Le Calvez (see [Lec2] and [Lec3]) and a recently developed accompanying orbit forcing theory (see [LecT]). The paper is organized as follows: the second section introduces the basic lemmas and results from the above mentioned Equivariant Brouwer Theory and the forcing results, as well as details the concept of rotation set for annulus homeomorphisms. Section 3 provides the necessary lemmas and results for obtaining Theorem B, Section 4 includes the proof of our main result and Section 5 provides two examples displaying how tight are the hypotheses of Theorem A.

2 Preliminary results

In this section, we state different results and definitions that will be useful in the rest of the article. The main tool will be the “forcing theory” introduced recently by P. Le Calvez and the second author (see [LecT] for more details). This theory will be expressed in terms of maximal isotopies, transverse foliations and transverse trajectories.

2.1 The open annulus

We will denote by \mathbb{T}^1 the quotient space \mathbb{R}/\mathbb{Z} and by $\mathbb{A} := \mathbb{T}^1 \times \mathbb{R}$ the open annulus. We will endow \mathbb{A} with its usual topology and orientation. We will denote by $\tilde{\pi} : \tilde{\mathbb{A}} := \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{A}$ the universal covering map of \mathbb{A} . We will write $\|\cdot\|$ for the usual norm in $\tilde{\mathbb{A}} := \mathbb{R} \times \mathbb{R}$. We will denote by $p_1 : \tilde{\mathbb{A}} \rightarrow \mathbb{R}$ the projection on the first coordinate. We note that every non-trivial covering automorphism of $\tilde{\pi}$ is an iterate of the translation defined by $\tilde{z} \mapsto \tilde{z} + (1, 0)$. A compact set $K \subset \mathbb{A}$ will be called *essential* if its complement has two unbounded connected components, and general set will be called essential if it contains an essential compact set.

2.2 Paths, lines, loops

Let M be an oriented surface. A *path* on M is a continuous map $\gamma : J \rightarrow M$ defined on an interval J of \mathbb{R} . In absence of ambiguity its image will also be called a path and denoted by γ . We will denote $\gamma^{-1} : -J \rightarrow M$ the path defined by $\gamma^{-1}(t) = \gamma(-t)$. If X and Y are two disjoint subsets of M , we will say that a path $\gamma : [a, b] \rightarrow M$ *joins* X to Y if $\gamma(a) \in X$ and $\gamma(b) \in Y$. A path $\gamma : J \rightarrow M$ is *proper* if the interval J is open and the preimage of every compact subset of M is compact. A *line* on M is an injective and proper path $\lambda : J \rightarrow M$, it inherits a natural orientation induced by the usual orientation of \mathbb{R} . A path $\gamma : \mathbb{R} \rightarrow M$ such that $\gamma(t+1) = \gamma(t)$ for every $t \in \mathbb{R}$ lifts a continuous map $\Gamma : \mathbb{T}^1 \rightarrow M$. We will say that Γ is a *loop* and γ its *natural lift*. If $n \geq 1$ is an integer, we denote Γ^n the loop lifted by the path $t \mapsto \gamma(nt)$.

2.3 Lines of the plane

Let λ be a line of the plane \mathbb{R}^2 . The complement of λ has two connected components, $R(\lambda)$ which is on the right of λ and $L(\lambda)$ which is on its left. If X and Y are two disjoint subsets of \mathbb{R}^2 , we will say that a line λ *separates* X from Y , if X and Y belong to different connected components of the complement of λ . Let us suppose that λ_0 and λ_1 are two disjoint lines of \mathbb{R}^2 . We will say that λ_0 and λ_1 are *comparable* if their right components are comparable for the inclusion. Note that λ_0 and λ_1 are not comparable if and only if λ_0 and $(\lambda_1)^{-1}$ are comparable.

Let us consider three lines λ_0 , λ_1 and λ_2 in \mathbb{R}^2 . We will say that λ_2 is *above* λ_1 relative to λ_0 (and λ_1 is *below* λ_2 relative to λ_0) if:

- the three lines are pairwise disjoint;
- none of the lines separates the two others;
- if γ_1 and γ_2 are two disjoint paths that join $z_1 = \lambda_0(t_1)$, $z_2 = \lambda_0(t_2)$ to $z'_1 \in \lambda_1$, $z'_2 \in \lambda_2$ respectively, and that do not meet the three lines but at the ends,

then $t_2 > t_1$. This notion does not depend on the orientation of λ_1 and λ_2 but depends of the orientation of λ_0 (see Figure 1).

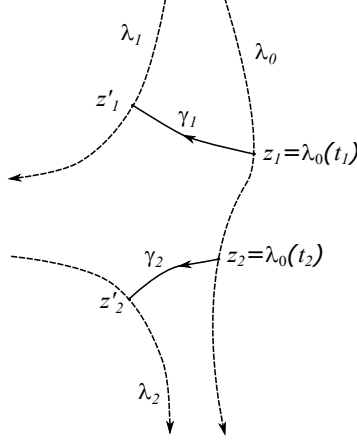

Figure 1: λ_2 is above λ_1 relative to λ_0 .

2.4 Transverse paths to surface foliations

Let M be an oriented surface. An *oriented singular foliation* \mathcal{F} on M we mean a closed set $\text{Sing}(\mathcal{F})$, called *the set of singularities of \mathcal{F}* , together with an oriented foliation \mathcal{F}' on the complement of $\text{Sing}(\mathcal{F})$, called *the domain of \mathcal{F}* and denoted by $\text{dom}(\mathcal{F})$, i.e. \mathcal{F}' is a partition of $\text{dom}(\mathcal{F})$ into connected oriented 1-manifolds (circles or lines) called *leaves of \mathcal{F}* , such that for every z in $\text{dom}(\mathcal{F})$ there exist an open neighborhood W of z , called *trivializing neighborhood* and an orientation preserving homeomorphism called *trivialization chart at z* , $h : W \rightarrow (0, 1)^2$ that sends the restricted foliation $\mathcal{F}|_W$ onto the vertical foliation oriented downward. If the set of singularities of \mathcal{F} is empty, we will say that the foliation \mathcal{F} is *non singular*. A subset of M is said to be *saturated* if it is the union of singular points and leaves of \mathcal{F} . For every $z \in \text{dom}(\mathcal{F})$ we will write ϕ_z for the leaf of \mathcal{F} that contains z , ϕ_z^+ for the positive half-leaf and ϕ_z^- for the negative one. We can define the α -limit and ω -limit sets of each leaf ϕ of \mathcal{F} as follows:

$$\alpha(\phi) := \bigcap_{z \in \phi} \overline{\phi_z^-}, \quad \text{and} \quad \omega(\phi) := \bigcap_{z \in \phi} \overline{\phi_z^+}.$$

Let ϕ be a leaf of \mathcal{F} . Suppose that a point $z \in \phi$ has a trivialization neighborhood W such that each leaf of \mathcal{F} contains no more than one leaf of $\mathcal{F}|_W$. In that case every point of ϕ satisfies the same property. If furthermore no closed leaf of \mathcal{F} meets W , we will say that ϕ is *wandering*.

A path $\gamma : J \rightarrow M$ is *positively transverse*¹ to \mathcal{F} if, its image does not meet the set of singularities of \mathcal{F} and if, for every $t_0 \in J$, and h trivialization chart at $\gamma(t_0)$ the application $t \mapsto \pi_1(h(\gamma(t)))$, where $\pi_1 : (0, 1)^2 \rightarrow (0, 1)$ is the projection on the first coordinate, is increasing in a neighborhood of t_0 . We note that if \tilde{M} is a covering space of M and $\tilde{\pi} : \tilde{M} \rightarrow M$ the covering projection, then \mathcal{F} can be naturally lifted to a singular foliation $\tilde{\mathcal{F}}$ of \tilde{M} such that $\text{dom}(\tilde{\mathcal{F}}) = \tilde{\pi}^{-1}(\text{dom}(\mathcal{F}))$. We will denote by $\widetilde{\text{dom}(\mathcal{F})}$ the universal covering space of $\text{dom}(\mathcal{F})$ and $\widetilde{\mathcal{F}}$ the foliation lifted from $\mathcal{F}|_{\text{dom}(\mathcal{F})}$. We note that $\widetilde{\mathcal{F}}$ is a non singular foliation of $\widetilde{\text{dom}(\mathcal{F})}$. Moreover if $\gamma : J \rightarrow \text{dom}(\mathcal{F})$ is *positively transverse* to \mathcal{F} , every lift $\tilde{\gamma} : J \rightarrow \tilde{M}$ of γ is *positively transverse* to the lifted foliation $\tilde{\mathcal{F}}$. In particular every lift $\tilde{\gamma} : J \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ of γ to the universal covering space $\widetilde{\text{dom}(\mathcal{F})}$ of $\text{dom}(\mathcal{F})$ is *positively transverse* to the lifted non singular foliation $\widetilde{\mathcal{F}}$.

2.4.1 \mathcal{F} -transverse intersection for non singular planar foliations

In this paragraph, we will suppose that \mathcal{F} is a non singular foliation on the plane \mathbb{R}^2 . We come recalling the following facts (see [HR]).

- Every leaf of \mathcal{F} is a wandering line;
- the space of leaves of \mathcal{F} , denoted by Σ , furnished with the quotient topology, inherits a structure of connected and simply connected one-dimensional manifold;
- Σ is Hausdorff if and only if the foliation \mathcal{F} is trivial, that means that it is the image of the vertical foliation by a planar homeomorphism, or equivalently if all the leaves of \mathcal{F} are comparable.

We will say that two transverse paths $\gamma_1 : J_1 \rightarrow \mathbb{R}^2$ and $\gamma_2 : J_2 \rightarrow \mathbb{R}^2$ are *\mathcal{F} -equivalent* if they satisfy the three following equivalent conditions:

- there exists an increasing homeomorphism $h : J_1 \rightarrow J_2$ such that for every $t \in J_1$ we have $\phi_{\gamma_1(t)} = \phi_{\gamma_2(h(t))}$;
- the paths γ_1 and γ_2 meet the same leaves of \mathcal{F} ;
- the paths γ_1 and γ_2 project onto the same path of Σ .

Moreover, if $J_1 = [a_1, b_1]$ and $J_2 = [a_2, b_2]$ are two compact segments, these conditions are equivalent to the next one:

- one has $\phi_{\gamma_1(a_1)} = \phi_{\gamma_2(a_2)}$ and $\phi_{\gamma_1(b_1)} = \phi_{\gamma_2(b_2)}$.

In that case, note that the leaves met by γ_1 are the leaves ϕ of \mathcal{F} such that $R(\phi_{\gamma_1(a_1)}) \subset R(\phi) \subset R(\phi_{\gamma_2(b_1)})$. If the context is clear, we just say that the

¹In the whole text “transverse” will mean “positively transverse”.

paths are equivalent and omit the dependence on \mathcal{F} .

Let $\gamma_1 : J_1 \rightarrow \mathbb{R}^2$ and $\gamma_2 : J_2 \rightarrow \mathbb{R}^2$ be two transverse paths such that there are $t_1 \in J_1$ and $t_2 \in J_2$ satisfying $\phi_{\gamma_1(t_1)} = \phi_{\gamma_2(t_2)} = \phi$. We will say that γ_1 and γ_2 *intersect \mathcal{F} -transversally and positively at ϕ* if there exist a_1, b_1 in J_1 satisfying $a_1 < t_1 < b_1$, and a_2, b_2 in J_2 satisfying $a_2 < t_2 < b_2$, such that:

- $\phi_{\gamma_2(a_2)}$ is below $\phi_{\gamma_1(a_1)}$ relative to ϕ ; and
- $\phi_{\gamma_2(b_2)}$ is above $\phi_{\gamma_1(b_1)}$ relative to ϕ .

See Figure 2.

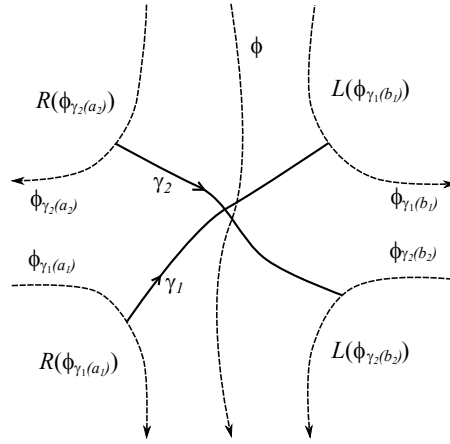

Figure 2: The paths γ_1 and γ_2 intersect \mathcal{F} -transversally and positively at ϕ .

Note that, if γ_1 intersects \mathcal{F} -transversally γ_2 , if γ'_1 is equivalent to γ_1 and γ'_2 is equivalent to γ_2 , then γ'_1 intersects \mathcal{F} -transversally γ'_2 . We will say that the equivalent class of γ_1 intersects transversally the equivalent class of γ_2 .

As none of the leaves ϕ , $\phi_{\gamma_1(a_1)}$, $\phi_{\gamma_2(a_2)}$ separates the two others, one deduces that

$$\phi_{\gamma_1(a_1)} \subset L(\phi_{\gamma_2(a_2)}), \quad \phi_{\gamma_2(a_2)} \subset L(\phi_{\gamma_1(a_1)}).$$

Similarly as none of the leaves ϕ , $\phi_{\gamma_1(b_1)}$, $\phi_{\gamma_2(b_2)}$ separates the two others, one deduces that

$$\phi_{\gamma_1(b_1)} \subset R(\phi_{\gamma_2(b_2)}), \quad \phi_{\gamma_2(b_2)} \subset R(\phi_{\gamma_1(b_1)}).$$

Observe that these properties remain true when a_1, a_2 are replaced by smaller parameters, b_1, b_2 by larger parameters and ϕ by any other leaf met by γ_1 and γ_2 . Note that γ_1 and γ_2 have at least one intersection point and that one can find two transverse paths γ'_1, γ'_2 equivalent to γ_1, γ_2 respectively, such that γ'_1 and γ'_2 have a unique intersection point, located in ϕ , with a topological

transverse intersection. Note that, if γ_1 and γ_2 are two paths that meet the same leaf ϕ of \mathcal{F} , then either they intersect \mathcal{F} -transversally, or one can find two transverse paths γ'_1, γ'_2 equivalent to γ_1, γ_2 respectively, with no intersection point.

2.4.2 \mathcal{F} -transverse intersection in the general case

Let us return now to the general case, i.e we will suppose that \mathcal{F} is an oriented singular foliation on an oriented surface M . All previous definitions can be extended in the case that every connected component of M is a plane and \mathcal{F} is non singular. We will say that two transverse paths $\gamma_1 : J_1 \rightarrow \text{dom}(\mathcal{F})$ and $\gamma_2 : J_2 \rightarrow \text{dom}(\mathcal{F})$ are \mathcal{F} -equivalent if there exist $\tilde{\gamma}_1 : J_1 \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ and $\tilde{\gamma}_2 : J_2 \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ lift of γ_1 and γ_2 respectively to the universal covering space $\widetilde{\text{dom}(\mathcal{F})}$ of $\text{dom}(\mathcal{F})$ that are $\widetilde{\text{dom}(\mathcal{F})}$ -equivalent. This implies that there exists an increasing homeomorphism $h : J_1 \rightarrow J_2$ such that for every $t \in J_1$ we have $\phi_{\gamma_1(t)} = \phi_{\gamma_2(h(t))}$. Nevertheless these two conditions are not equivalent (see Figure 3 from [LecT]). One can prove that γ_1 and γ_2 are \mathcal{F} -equivalent if and only if, there exists a *holonomic homotopy* between γ_1 and γ_2 , that is, if there exist a continuous transformation $H : J_1 \times [0, 1] \rightarrow \text{dom}(\mathcal{F})$ and an increasing homeomorphism $h : J_1 \rightarrow J_2$ satisfying:

- $H(t, 0) = \gamma_1(t), H(t, 1) = \gamma_2(h(t));$ and
- for every $t \in J_1$ and every $s_1, s_2 \in [0, 1]$, we have $\phi_{H(t, s_1)} = \phi_{H(t, s_2)}$.

We will say that a loop $\Gamma : \mathbb{T}^1 \rightarrow \text{dom}(\mathcal{F})$ is positively transverse to \mathcal{F} if it is the case for its natural lift $\gamma : \mathbb{R} \rightarrow \widetilde{\text{dom}(\mathcal{F})}$. We will say that two loops $\Gamma_1 : J_1 \rightarrow \text{dom}(\mathcal{F})$ and $\Gamma_2 : J_2 \rightarrow \text{dom}(\mathcal{F})$ are \mathcal{F} -equivalent if there exist two lifts $\tilde{\gamma}_1 : \mathbb{R} \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ and $\tilde{\gamma}_2 : \mathbb{R} \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ of Γ_1 and Γ_2 respectively to the universal covering space $\widetilde{\text{dom}(\mathcal{F})}$ of $\text{dom}(\mathcal{F})$, a covering automorphism T and an orientation preserving homeomorphism $h : \mathbb{R} \rightarrow \mathbb{R}$, such that, for every $t \in \mathbb{R}$, we have

$$\tilde{\gamma}_1(t+1) = T(\tilde{\gamma}_1(t)), \tilde{\gamma}_2(t+1) = T(\tilde{\gamma}_2(t)), h(t+1) = h(t)+1, \phi_{\tilde{\gamma}_2(h(t))} = \phi_{\tilde{\gamma}_1(t)}.$$

We note that for every integer $n \geq 1$ the loops Γ_1^n and Γ_2^n are \mathcal{F} -equivalent if this is the case for Γ_1 and Γ_2 . If two loops Γ_1 and Γ_2 are \mathcal{F} -equivalent, then there exists a holonomic homotopy between them and therefore they are freely homotopic in $\text{dom}(\mathcal{F})$. Nevertheless the converse does not hold (see Figure 4 from [LecT]).

Let $\gamma_1 : J_1 \rightarrow M$ and $\gamma_2 : J_2 \rightarrow M$ be two transverse paths that meet a common leaf $\phi = \phi_{\gamma_1(t_1)} = \phi_{\gamma_2(t_2)}$. We will say that γ_1 and γ_2 *intersect \mathcal{F} -transversally at ϕ* if there exist paths $\tilde{\gamma}_1 : J_1 \rightarrow \widetilde{\text{dom}(\mathcal{F})}$ and $\tilde{\gamma}_2 : J_2 \rightarrow \widetilde{\text{dom}(\mathcal{F})}$, lifting γ_1 and γ_2 , with a common leaf $\tilde{\phi} = \phi_{\tilde{\gamma}_1(t_1)} = \phi_{\tilde{\gamma}_2(t_2)}$ that lifts ϕ , and intersecting $\tilde{\mathcal{F}}$ -transversally at $\tilde{\phi}$. Here again, we can give sign to the intersection. As explained in the last subsection, there exist $t'_1 \in J_1$ and $t'_2 \in J_2$

such that $\gamma_1(t'_1) = \gamma_2(t'_2)$ and such that γ_1 and γ_2 intersect \mathcal{F} -transversally at $\phi_{\gamma_1(t'_1)} = \phi_{\gamma_2(t'_2)}$. In this case we will say that γ_1 and γ_2 intersect \mathcal{F} -transversally at $\gamma_1(t'_1) = \gamma_2(t'_2)$. In the case where $\gamma_1 = \gamma_2$ we will talk of a \mathcal{F} -transverse self-intersection. A transverse path γ has a \mathcal{F} -transverse self-intersection if for every lift $\tilde{\gamma}$ to the universal covering space of the domain of the foliation, there exists a non trivial covering automorphism T such that $\tilde{\gamma}$ and $T(\tilde{\gamma})$ have a $\tilde{\mathcal{F}}$ -transverse intersection. We will often use the following fact. Let $\gamma_1 : J_1 \rightarrow M$ and $\gamma_2 : J_2 \rightarrow M$ be two transverse paths that meet a common leaf $\phi = \phi_{\gamma_1(t_1)} = \phi_{\gamma_2(t_2)}$. If J'_1, J'_2 are two sub-intervals of J_1 and J_2 that contain t_1, t_2 respectively, and if $\gamma_1|_{J'_1}$ and $\gamma_2|_{J'_2}$ intersect \mathcal{F} -transversally at ϕ , then γ_1 and γ_2 intersect \mathcal{F} -transversally at ϕ .

Similarly, let Γ be a loop that is transverse to \mathcal{F} and γ its natural lift. If γ intersects \mathcal{F} -transversally a transverse path γ' at a leaf ϕ , we will say that Γ and γ' intersect \mathcal{F} -transversally at ϕ . Moreover if γ' is the natural lift of a transverse loop Γ' , we will say that Γ and Γ' intersect \mathcal{F} -transversally at ϕ . Here again we can talk of self-intersection.

A transverse path $\gamma : \mathbb{R} \rightarrow M$ will be called \mathcal{F} -positively recurrent if for every segment J of \mathbb{R} and every $t \in \mathbb{R}$ there exists a segment J' contained in $[t, +\infty)$ such that $\gamma|_{J'}$ is \mathcal{F} -equivalent to $\gamma|_J$. It will be called \mathcal{F} -negatively recurrent if for every segment J of \mathbb{R} and every $t \in \mathbb{R}$ there exists a segment J' contained in $(-\infty, t]$ such that $\gamma|_{J'}$ is \mathcal{F} -equivalent to $\gamma|_J$. It will be called \mathcal{F} -bi-recurrent if it is both \mathcal{F} -positively and \mathcal{F} -negatively recurrent. We note that, if $\gamma : \mathbb{R} \rightarrow M$ and $\gamma' : \mathbb{R} \rightarrow M$ are \mathcal{F} -equivalent and if γ is \mathcal{F} -positively recurrent (or \mathcal{F} -negatively recurrent), then so is γ' . We will say that a \mathcal{F} -equivalent class is positively recurrent (negatively recurrent or bi-recurrent) if some representative of the class is \mathcal{F} -positively recurrent (respectively \mathcal{F} -negatively recurrent, \mathcal{F} -bi-recurrent).

The following result describes paths with no transverse self-intersection on the two-dimensional sphere.

Proposition 2.1 ([LecT]). *Let \mathcal{F} be an oriented singular foliation on \mathbb{S}^2 and let $\gamma : \mathbb{R} \rightarrow \mathbb{S}^2$ be a \mathcal{F} -bi-recurrent transverse path. The following properties are equivalent:*

- (i) γ has no \mathcal{F} -transverse self-intersection;
- (ii) there exists a transverse simple loop Γ' such that γ is equivalent to the natural lift γ' of Γ' ;
- (iii) the set $U = \bigcup_{t \in \mathbb{R}} \phi_{\gamma(t)}$ is an open annulus.

The following result describes paths that are transverse to a transverse line in \mathbb{R}^2 . We note that if λ is a line which is transverse to an oriented singular foliation \mathcal{F} on the plane \mathbb{R}^2 , then λ meets every leaf at most once. One can define the sets $r(\lambda)$ (resp. $l(\lambda)$) as the union of leaves of \mathcal{F} that are included in

$R(\lambda)$ (resp. $L(\lambda)$). We note that these sets do not depend on the choice of λ in the equivalent class.

Lemma 2.2 ([LecT]). *Let \mathcal{F} be an oriented singular foliation on \mathbb{R}^2 . Let γ be a \mathcal{F} -transverse path that is a line and let γ' be a \mathcal{F} -transverse path. If γ and γ' do not intersect \mathcal{F} -transversally, then γ' cannot meet both $r(\gamma)$ and $l(\gamma)$.*

2.5 Maximal isotopies, transverse foliations, admissible paths

2.5.1 Isotopies, maximal isotopies

Let M be an oriented surface. Let f be a homeomorphism of M . An *identity isotopy* of f is a path that joins the identity to f in the space of homeomorphisms of M , furnished with the C^0 -topology. We will say that f is *isotopic to the identity* if the set of identity isotopies of f is not empty. Let $I = (f_t)_{t \in [0,1]}$ be an identity isotopy of f . Given $z \in M$ we can define the *trajectory* of z as the path $I(z) : t \mapsto f_t(z)$. More generally, for every integer $n \geq 1$ we define $I^n(z) = \prod_{0 \leq k < n} I(f^k(z))$ by concatenation. We will also use the following notations

$$I^{\mathbb{N}}(z) = \prod_{k \in \mathbb{N}} I(f^k(z)), \quad I^{-\mathbb{N}}(z) = \prod_{k \in \mathbb{N}} I(f^{-k}(z)), \quad I^{\mathbb{Z}}(z) = \prod_{k \in \mathbb{Z}} I(f^k(z)).$$

The last path will be called the *whole trajectory* of z . One can define the fixed point set of I as $\text{Fix}(I) = \bigcap_{t \in [0,1]} \text{Fix}(f_t)$, which is the set of points with trivial whole trajectory. The complement of $\text{Fix}(I)$ will be called the *domain* of I , and it will be denoted by $\text{dom}(I)$.

In general, let us say that an identity isotopy of f is a maximal isotopy, if there is no fixed point of f whose trajectory is contractible relative to the fixed point set of I . A very recent result of F. Béguin, S. Crovisier and F. Le Roux (see [BCL2]) asserts that such an isotopy always exists if f is isotopic to the identity (a slightly weaker result was previously proved by O. Jaulent (see [J])). Here we prefer to follow [BCL2], because Jaulent's Theorem about existence of maximal isotopies can be stated in the following much more natural form.

Theorem 2.3 ([J], [BCL2]). *Let M be an oriented surface. Let f be a homeomorphism of M which is isotopic to the identity and let I' be an identity isotopy of f . Then there exists an identity isotopy I of f such that:*

- (i) $\text{Fix}(I') \subset \text{Fix}(I)$;
- (ii) I is homotopic to I' relative to $\text{Fix}(I')$;
- (iii) there is no point $z \in \text{Fix}(f) \setminus \text{Fix}(I)$ whose trajectory $I(z)$ is homotopic to zero in $M \setminus \text{Fix}(I)$.

We will say that an identity isotopy I satisfying the conclusion of Theorem 2.3 is a *maximal isotopy (larger than I')*. We note that the last condition of the above theorem can be stated in the following equivalent form:

(iii') if $\tilde{I} = (\tilde{f}_t)_{t \in [0,1]}$ is the identity isotopy that lifts $I|_{M \setminus \text{Fix}(I)}$ to the universal covering space of $M \setminus \text{Fix}(I)$, then \tilde{f}_1 is fixed point free.

The typical example of an isotopy I verifying condition (iii) is the restricted family $I = (f_t)_{t \in [0,1]}$ of a topological flow $(f_t)_{t \in \mathbb{R}}$ on M . Indeed, one can lift the flow $(f_t|_{M \setminus \text{Fix}(I)})_{t \in \mathbb{R}}$ as a flow $(\tilde{f}_t)_{t \in \mathbb{R}}$ on the universal covering space of $M \setminus \text{Fix}(I)$. This flow has no fixed point and consequently no periodic point. So \tilde{f}_1 is fixed point free, which exactly means that condition (iii) is fulfilled.

2.5.2 Transversal foliations

Let f be a homeomorphism of the plane \mathbb{R}^2 which preserves the orientation. We will say that a line λ of \mathbb{R}^2 is a *Brouwer line of f* if $f(\lambda) \subset L(\lambda)$ and $f^{-1}(\lambda) \subset R(\lambda)$. If f is fixed point free the main result to the Brouwer Theory is the Plane Translation Theorem: every point of the plane lies on a Brouwer line of f (see [Bu]). Let us recall now the equivariant foliation version of this theorem due to P. Le Calvez (see [Lec3]). Suppose that f is a homeomorphism that is isotopic to the identity on an oriented surface M . Let I be a maximal identity isotopy of f and let $\tilde{I} = (\tilde{f}_t)_{t \in [0,1]}$ be the identity isotopy that lifts I to the universal covering space $\widetilde{\text{dom}(I)}$ of $\text{dom}(I)$. We recall that the homeomorphism $\tilde{f} = \tilde{f}_1$ is fixed point free. Suppose that $\text{dom}(I)$ is connected, in this case $\widetilde{\text{dom}(I)}$ is a plane and we have that there exists a non singular oriented foliation $\tilde{\mathcal{F}}$ on $\widetilde{\text{dom}(I)}$, invariant by the covering automorphisms, whose leaves are Brouwer lines of \tilde{f} (see [Lec3]). We have the following result, still true in case that $\text{dom}(I)$ is not connected.

Theorem 2.4 ([Lec3]). *Let M be an oriented surface. Let f be a homeomorphism of M which is isotopic to the identity and let I be a maximal identity isotopy of f . Then there exists an oriented singular foliation \mathcal{F} with $\text{dom}(\mathcal{F}) = \text{dom}(I)$, such that for every $z \in \text{dom}(I)$ the trajectory $I(z)$ is homotopic, relative to the endpoints, in $\text{dom}(\mathcal{F})$ to a positively transverse path to \mathcal{F} and this path is unique defined up to equivalence.*

We will say that a foliation \mathcal{F} satisfying the conclusion of Theorem 2.4 is *transverse to I* . Observe that if \tilde{M} is a covering space of M and $\tilde{\pi} : \tilde{M} \rightarrow M$ the covering projection, a foliation \mathcal{F} transverse to a maximal identity isotopy I lifts to a foliation $\tilde{\mathcal{F}}$ transverse to the lifted isotopy \tilde{I} .

Given $z \in M$ we will write $I_{\mathcal{F}}(z)$ for the class of paths that are positively transverse to \mathcal{F} , that join z to $f(z)$ and that are homotopic in $\text{dom}(\mathcal{F})$ to $I(z)$, relative to the endpoints. We will also use the notation $I_{\mathcal{F}}(z)$ for every path in this class and we will call it the *transverse trajectory of z* . More generally, for

every integer $n \geq 1$ we can define $I_{\mathcal{F}}^n(z) = \prod_{0 \leq k < n} I(f^k(z))$ by concatenation, that is either a transverse path passing through the points $z, f(z), \dots, f^n(z)$, or a set of such paths. We will also use the following notations

$$I_{\mathcal{F}}^{\mathbb{N}}(z) = \prod_{k \in \mathbb{N}} I(f^k(z)), \quad I_{\mathcal{F}}^{-\mathbb{N}}(z) = \prod_{k \in \mathbb{N}} I(f^{-k}(z)), \quad I_{\mathcal{F}}^{\mathbb{Z}}(z) = \prod_{k \in \mathbb{Z}} I(f^k(z)).$$

The last path will be called the *whole transverse trajectory* of z .

If z is a periodic point of f of period q , there exists a transverse loop Γ whose natural lift γ satisfies $\gamma|_{[0,1]} = I_{\mathcal{F}}^q(z)$. We will say that a transverse loop *is associated to* z if it is \mathcal{F} -equivalent to Γ . We note that this definition does not depend on the choices of the trajectory $I_{\mathcal{F}}(f^k(z))$, with $0 \leq k < q$.

Let us state the following result that will be useful later.

Lemma 2.5 ([LecT]). *Fix $z \in \text{dom}(I)$, an integer $n \geq 1$, and parameterize $I_{\mathcal{F}}^n(z)$ by $[0, 1]$. For every $0 < a < b < 1$, there exists a neighborhood V of z such that for every z' in V , the path $I_{\mathcal{F}}^n(z)|_{[a,b]}$ is equivalent to a subpath of $I_{\mathcal{F}}^n(z')$. Moreover, there exists a neighborhood W of z such that for every z' and z'' in W , the path $I_{\mathcal{F}}^n(z')$ is equivalent to a subpath of $I_{\mathcal{F}}^{n+2}(f^{-1}(z''))$.*

An immediate consequence of the previous lemma is the fact that, if z in $\text{dom}(I)$ is positively recurrent, negatively recurrent or bi-recurrent, then the whole transverse trajectory of z , $I_{\mathcal{F}}^{\mathbb{Z}}(z)$, is \mathcal{F} -positively recurrent, \mathcal{F} -negatively recurrent or \mathcal{F} -bi-recurrent respectively.

2.5.3 Admissible paths

We will say that a transverse path $\gamma : [a, b] \rightarrow \text{dom}(I)$ is *admissible of order n* (n is an integer larger than 1) if it is equivalent to a path $I_{\mathcal{F}}^n(z)$, z in $\text{dom}(I)$. It means that if $\tilde{\gamma} : [a, b] \rightarrow \widetilde{\text{dom}(I)}$ is a lift of γ , then there exists a point \tilde{z} in $\widetilde{\text{dom}(I)}$ such that $\tilde{z} \in \phi_{\tilde{\gamma}(a)}$ and $\tilde{f}^n(\tilde{z}) \in \phi_{\tilde{\gamma}(b)}$, or equivalently, that

$$\tilde{f}^n(\phi_{\tilde{\gamma}(a)}) \cap \phi_{\tilde{\gamma}(b)} \neq \emptyset.$$

We note that if f preserves a Borel probability measure of full support, then the set of bi-recurrent points is dense in M . It follows from Lemma 2.5 that every admissible transverse path is equivalent to a subpath of a bi-recurrent one.

We will say that a transverse path $\gamma : [a, b] \rightarrow \text{dom}(I)$ is *admissible of order $\leq n$* (n is an integer larger than 1) if it is a subpath of an admissible path of order n . More generally, we will say that a transverse path $\gamma : J \rightarrow \text{dom}(I)$ defined on an interval of \mathbb{R} is *admissible* if for every segment $[a, b] \subset J$, there exists an integer $n \geq 1$ such that $\gamma|_{[a,b]}$ is admissible of order $\leq n$. Similarly, we will say that a transverse loop Γ is admissible if its natural lift is admissible. The

following lemma states that for subpaths of an admissible transverse loop with a \mathcal{F} -transverse self-intersection there is no difference between being of order $\leq n$ and being of order n .

Lemma 2.6 ([LecT]). *Let Γ be an admissible transverse loop with a \mathcal{F} -transverse self-intersection and let $\gamma : \mathbb{R} \rightarrow M$ be its natural lift. For every segment $[a, b] \subset \mathbb{R}$, if $\gamma|_{[a, b]}$ is admissible of order $\leq n$, then $\gamma|_{[a, b]}$ is admissible of order n .*

2.5.4 The fundamental proposition

The fundamental proposition (Proposition 20 from [LecT]) is a result about maximal isotopies and transverse foliations that permits us to construct new admissible paths from a pair of admissible paths.

Proposition 2.7 ([LecT]). *Suppose that $\gamma_1 : [a_1, b_1] \rightarrow M$ and $\gamma_2 : [a_2, b_2] \rightarrow M$ are two transverse paths that intersect \mathcal{F} -transversally at $\gamma_1(t_1) = \gamma_2(t_2)$. If γ_1 is admissible of order n_1 and γ_2 is admissible of order n_2 , then the paths $\gamma_1|_{[a_1, t_1]}\gamma_2|_{[t_2, b_2]}$ and $\gamma_2|_{[a_2, t_2]}\gamma_1|_{[t_1, b_1]}$ are admissible of order $n_1 + n_2$.*

One deduces immediately the following result.

Lemma 2.8 ([LecT]). *Let $\gamma_i : [a_i, b_i] \rightarrow M$, $1 \leq i \leq r$, be a family of $r \geq 2$ transverse paths. We suppose that for every $i \in \{1, \dots, r\}$ there exist $s_i \in [a_i, b_i]$ and $t_i \in [a_i, b_i]$ such that:*

- (i) $\gamma_i|_{[s_i, b_i]}$ and $\gamma_{i+1}|_{[a_{i+1}, t_{i+1}]}$ intersect \mathcal{F} -transversally at $\gamma_i(t_i) = \gamma_{i+1}(s_{i+1})$ if $i < r$;
- (ii) one has $s_1 = a_1 < t_1 < b_1$, $a_r < s_r < t_r = b_r$ and $a_i < s_i < t_i < b_i$ if $1 < i < r$;
- (iii) γ_i is admissible of order n_i .

Then $\prod_{1 \leq i \leq r} \gamma_i|_{[s_i, t_i]}$ is admissible of order $\sum_{1 \leq i \leq r} n_i$.

The following result is a consequence of Proposition 23 from [LecT].

Lemma 2.9 ([LecT]). *Let $\gamma : [a, b] \rightarrow M$ be a transverse path admissible of order n . Then there exists $\gamma' : [a, b] \rightarrow M$ a transverse path, also admissible of order n , such that γ' has no \mathcal{F} -transverse self-intersection and $\phi_{\gamma(a)} = \phi_{\gamma'(a)}$, $\phi_{\gamma(b)} = \phi_{\gamma'(b)}$.*

2.5.5 Realizability of transverse loops

Let Γ be a \mathcal{F} -transverse loop and let $\gamma : \mathbb{R} \rightarrow M$ be its natural lift. We will say that Γ is *linearly admissible of order q* (q is an integer larger than 1) if it satisfies the following property (note that every equivalent loop will satisfy the same property):

(Q_q) : there exist two sequences $(r_k)_{k \in \mathbb{N}}$ and $(s_k)_{k \in \mathbb{N}}$ of natural integers satisfying

$$\lim_{k \rightarrow +\infty} r_k = \lim_{k \rightarrow +\infty} s_k = +\infty, \quad \limsup_{k \rightarrow +\infty} r_k/s_k \geq 1/q$$

such that for every integer $k \geq 1$, $\gamma|_{[0, r_k]}$ is admissible of order $\leq s_k$.

In [LecT], the authors proved that in many situations the existence of a transverse loop that satisfies property (Q_q) implies the existence of infinitely many periodic orbit. In our setting, we can state their result as follows.

Proposition 2.10 ([LecT]). *Let Γ be a linearly admissible transverse loop of order $q \geq 1$ that has a \mathcal{F} -transverse self-intersection. Then for every rational number $r/s \in (0, 1/q]$, written in an irreducible way, the loop Γ^r is associated to a periodic orbit of period s .*

The following result will permit to apply the previous proposition.

Lemma 2.11 ([LecT]). *Let $\gamma_1, \gamma_2 : \mathbb{R} \rightarrow M$ be two admissible positively recurrent paths (possibly equal) with a \mathcal{F} -transverse intersection, and let I_1 and I_2 be two real segments. Then there exists a linearly admissible transverse loop Γ with a \mathcal{F} -transverse self-intersection, such that $\gamma_1|_{I_1}$ and $\gamma_2|_{I_2}$ are equivalent to subpaths of the natural lift of Γ .*

2.6 The rotation set

In this paragraph, we consider a homeomorphism f of the open annulus $\mathbb{A} = \mathbb{T}^1 \times \mathbb{R}$ which is isotopy to the identity. Let \check{f} be a lift of f to $\check{\mathbb{A}}$. We will give the definition of the *rotation set of \check{f}* due to J. Franks (see [F3]). Given a compact set K of \mathbb{A} , a number $\rho \in \overline{\mathbb{R}} := \mathbb{R} \cup \{+\infty\} \cup \{-\infty\}$ belongs to the *rotation set of \check{f} relative to K* , denoted by $\text{Rot}_K(\check{f})$, if there exist a sequence of points $(\check{z}_k)_{k \in \mathbb{N}}$ and a sequence of integers $(n_k)_{k \in \mathbb{N}}$ which goes to $+\infty$ such that for every $k \in \mathbb{N}$, \check{z}_k and $\check{f}^{n_k}(\check{z}_k)$ belong to $\check{\pi}^{-1}(K)$ and

$$\rho = \lim_{k \rightarrow +\infty} \frac{1}{n_k} (p_1(\check{f}^{n_k}(\check{z}_k)) - p_1(\check{z}_k)).$$

The *rotation set of \check{f}* is defined as

$$\text{Rot}(\check{f}) := \overline{\bigcup_K \text{Rot}_K(\check{f})},$$

where K is a compact set of \mathbb{A} and the “closure” is taken in $\overline{\mathbb{R}}$. We note that for every $p \in \mathbb{Z}$ and every $q \in \mathbb{Z}$, the map $\check{f}^q + (p, 0)$ defined by $\check{z} \mapsto \check{f}^q(\check{z}) + (p, 0)$ is a lift of f^q and we have $\text{Rot}(\check{f}^q + (p, 0)) = q \text{Rot}(\check{f}) + p$. We note that the first author proved that this set is always an interval (see [C]). We recall that this result has been known for measure-preserving homeomorphisms (for example, see [Lec3], Theorem 9.1 for a proof that uses maximal isotopies and transverse foliations). In this case, we obtain the following theorem.

Theorem 2.12 ([F3], [Lec3]). *Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure of full support. Let \check{f} be a lift of f to $\check{\mathbb{A}}$. Then for every irreducible rational number r/s that belongs to the interior of $\text{Rot}(\check{f})$ there exists a point \check{z} in $\check{\mathbb{A}}$ such that $\check{f}^s(\check{z}) = \check{z} + (r, 0)$.*

Moreover using some ergodic theoretical arguments due to P. Le Calvez (see [Lec1]), we obtain the following result (see [BCL1]).

Lemma 2.13 ([BCL1]). *Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure μ of full support. Let \check{f} be a lift of f to $\check{\mathbb{A}}$. Suppose that \check{f} does not have fixed points. Then the rotation set $\text{Rot}(\check{f})$ is either contained in $[-\infty, 0]$ or in $[0, +\infty]$. Furthermore, μ -almost every point has a non-zero rotation number.*

We note that the second part of this lemma implies that if the rotation set $\text{Rot}(\check{f})$ is reduced to a rational number r/s , written in an irreducible way, then there exists a point \check{z} in $\check{\mathbb{A}}$ such that $\check{f}^s(\check{z}) = \check{z} + (r, 0)$.

2.7 A classical Brouwer theory lemma

In this section we will prove a general proposition that play a key role in the proof of Theorem A. We will use classical properties of translations, derived from Brouwer Theory. We denote by $\mathbb{A} := \mathbb{T}^1 \times \mathbb{R}$ the open annulus. We endow the annulus with its usual topology and orientation. Let $\tilde{\pi} : \mathbb{R}^2 \rightarrow \mathbb{A}$ be the universal covering of the open annulus \mathbb{A} . We recall that every non-trivial covering automorphism of $\tilde{\pi}$ is an iterate of the translation $z \mapsto z + (1, 0)$. The following lemma is a direct consequence of Lemma 3.1 of [Bw].

Lemma 2.14. *Let $K \subset \mathbb{R}^2$ be an arcwise connected set such that $K \cap (K + (1, 0)) = \emptyset$. Then for every $j \in \mathbb{Z}$ with $j \neq 0$, we have that $K \cap (K + (j, 0)) = \emptyset$.*

The following proposition is Lemma 12 from [GKT]. We outline here the proof.

Proposition 2.15 ([GKT]). *Let δ be a segment such that $\delta \cap (\delta + (1, 0)) = \emptyset$. Let $\gamma : [0, 1] \rightarrow \mathbb{R}^2$ be a path satisfying $\gamma(0) \in \delta$ and $\gamma(1) \in \delta + (j, 0)$ for some $j \in \mathbb{N}$. Then*

- (i) *the path γ meets $\gamma + (1, 0)$, or*
- (ii) *for every $i \in \{0, \dots, j\}$, the path γ meets $\delta + (i, 0)$.*

Proof. Suppose that Assertion (i) does not hold, that is $\gamma \cap (\gamma + (1, 0)) = \emptyset$. Fix $i \in \{0, \dots, j\}$, we will prove that $\gamma \cap (\delta + (i, 0)) \neq \emptyset$. Consider

$$t_0 := \max \left\{ t \in [0, 1] : \gamma(t) \in \bigcup_{n \geq 0} (\delta + (i - n, 0)) \right\},$$

$$t_1 := \min \left\{ t \in [t_0, 1] : \gamma(t) \in \bigcup_{n \geq 1} (\delta + (i + n, 0)) \right\},$$

and let $i_0 \geq 0$ and $j_0 \geq 1$ be integers such that $\gamma(t_0) \in \delta + (i - i_0, 0)$ and $\gamma(t_1) \in \delta + (i + j_0, 0)$. Finally, let

$$K := (\delta + (i - i_0, 0)) \cup \gamma([t_0, t_1]) \cup (\delta + (i + j_0, 0)),$$

which is an arcwise connected set. We prove by contradiction that $i_0 = 0$ and $j_0 = 1$, i.e. we assume that $i_0 + j_0 > 1$ and we seek a contradiction. Note first that by construction, the path $\gamma([t_0, t_1])$ is disjoint from $\bigcup_{n \in \mathbb{Z}} (\delta + (n, 0))$. Since $\delta \cap (\delta + (1, 0)) = \emptyset$, it follows from Lemma 2.14 that for every non-zero integer n we have $\delta \cap (\delta + (n, 0)) = \emptyset$, and so $\delta + (i - i_0, 0)$ is disjoint from $\delta + (i + j_0, 0)$ (because $i_0 + j_0 > 1$). Therefore we have that K is disjoint from $K + (1, 0)$, and so again by Lemma 2.14 we have that for every non-zero integer n , K is disjoint from $K + (n, 0)$. But $i_0 + j_0 > 1$, and clearly $K + (i_0 + j_0, 0)$ intersects K . This contradiction shows that $i_0 + j_0 = 1$, i.e. $i_0 = 0$ and $j_0 = 1$.

Since $\gamma(t_0) \in \gamma \cap (\delta + (i - i_0, 0)) = \gamma \cap (\delta + (i, 0))$, we have shown that γ intersects $\delta + (i, 0)$, i.e. Assertion (ii) holds. This completes the proof of the proposition. \blacksquare

3 Existence of non-contractible periodic points for homeomorphisms of the open annulus

In order to prove Theorem A, we prove a recurrence type theorem in the lifted dynamics of a homeomorphism of the open annulus that is isotopic to the identity. Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and let I' be an identity isotopy of f . A periodic point $z \in \mathbb{A}$ of period $q \in \mathbb{N}$ is said *contractible (with respect to the isotopy I')* if the loop $I'^q(z)$ is homotopically trivial in \mathbb{A} , otherwise it is said *non-contractible (with respect to the isotopy I')*. In this section we examine some conditions that ensure the existence of non-contractible periodic points of arbitrarily large prime period. We have the following result.

Theorem B. *Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure of full support. Let \check{f} be a lift of f to $\check{\mathbb{A}}$. Suppose that \check{f} has fixed points. Then*

- (1) *either there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in (0, 1/q]$, the map $\check{z} \mapsto \check{f}^s(\check{z}) + (r, 0)$ or $\check{z} \mapsto \check{f}^s(\check{z}) - (r, 0)$ has a fixed point;*
- (2) *or for every recurrent point $z \in \mathbb{A}$, there exists an open topological disk V containing z such that: if \check{V} is a lift of V and \check{z} is the lift of z contained in \check{V} , then for every integer n satisfying $f^n(z) \in V$, we have $\check{f}^n(\check{z}) \in \check{V}$.*

As an immediate consequence, we have the following result for irrotational homeomorphisms of \mathbb{A} . A homeomorphism f of \mathbb{A} will be said irrotational if it is isotopic to the identity and its rotation set is reduced to an integer number. We will call irrotational lift of f to the lift \tilde{f} of f satisfying $\text{Rot}(\tilde{f}) = \{0\}$.

Theorem C. *Let f be an irrotational homeomorphism of \mathbb{A} which preserves a Borel probability measure of full support. Let \tilde{f} be the irrotational lift of f . Then the set of bi-recurrent points of \tilde{f} is dense in $\tilde{\mathbb{A}}$. In particular \tilde{f} is non-wandering.*

Proof of Theorem B. Let \tilde{I}' be an identity isotopy of f , such that its lift to $\tilde{\mathbb{A}}$, \tilde{I}' , is an identity isotopy of \tilde{f} . By Theorem 2.3 one can find a maximal identity isotopy I of f larger than I' . It can be lifted to an isotopy \tilde{I} with $\text{dom}(\tilde{I}) = \tilde{\pi}^{-1}(\text{dom}(I))$. This isotopy is a maximal identity isotopy of \tilde{f} larger than \tilde{I}' . By Theorem 2.4 one can find an oriented singular foliation \mathcal{F} which is transverse to I , its lift to $\tilde{\mathbb{A}}$, denoted by $\tilde{\mathcal{F}}$, is transverse to \tilde{I} on $\tilde{\mathbb{A}}$. Theorem B is a consequence of the following proposition which will be proved below.

Proposition 3.1. *Suppose that f has contractible fixed points (with respect to I) and that one of the following conditions is satisfied:*

- (i) *There exist a linearly admissible transverse loop Γ with a \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of the natural lift of Γ to $\tilde{\mathbb{A}}$ and a non-zero integer j such that for every $t \in \mathbb{R}$ we have $\tilde{\gamma}(t+1) = \tilde{\gamma}(t) + (j, 0)$.*
- (ii) *There exist a linearly admissible transverse loop Γ with a \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of the natural lift of Γ to $\tilde{\mathbb{A}}$ and a non-zero integer j such that $\tilde{\gamma}$ is a loop $\tilde{\Gamma}$ and $\tilde{\Gamma}$ and $\tilde{\Gamma} + (j, 0)$ have a $\tilde{\mathcal{F}}$ -transverse intersection.*
- (iii) *There exist an admissible \mathcal{F} -bi-recurrent transverse path γ which has no \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of γ to $\tilde{\mathbb{A}}$, a leaf $\tilde{\phi}$ of $\tilde{\mathcal{F}}$ and a non-zero integer j such that $\tilde{\gamma}$ crosses both $\tilde{\phi}$ and $\tilde{\phi} + (j, 0)$.*

Then there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in (0, 1/q]$, the map $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) + (r, 0)$ or $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) - (r, 0)$ has a fixed point. In particular f has non-contractible periodic point of arbitrarily large prime period.

Remark 1. If above condition (ii) holds, we will prove that there exists an integer $q \geq 1$ such that for every irreducible rational number $r/s \in [-1/q, 1/q]$ the map $\tilde{z} \mapsto \tilde{f}^s(\tilde{z}) + (r, 0)$ has a fixed point.

3.1 Some conditions that ensure the existence of non-contractible periodic points

In this subsection we examine some conditions that allow us to apply Proposition 3.1, and so to ensure the existence of non-contractible periodic points of arbitrarily large prime period. Let \mathcal{F} be an oriented singular foliation on \mathbb{A} .

We coming by recall some facts about \mathcal{F} -bi-recurrent transverse path on \mathbb{A} . Let $\gamma : J \subset \mathbb{R} \rightarrow \mathbb{A}$ be a \mathcal{F} -bi-recurrent transverse path. The path γ being bi-recurrent, one can find real numbers $a < b$ such that $\phi_{\gamma(a)} = \phi_{\gamma(b)}$. Replacing γ by an equivalent transverse path, one can suppose that $\gamma(a) = \gamma(b)$. Let Γ be the loop naturally defined by the closed path $\gamma|_{[a,b]}$. We know that every leaf that meet Γ is wandering (see [LecT] for more details) and consequently, if t and t' are sufficiently close, one has $\phi_{\Gamma(t)} \neq \phi_{\Gamma(t')}$. Moreover, because Γ is positively transverse to \mathcal{F} , one cannot find an increasing sequence $(a_n)_{n \in \mathbb{N}}$ and a decreasing sequence $(b_n)_{n \in \mathbb{N}}$, such that $\phi_{\gamma(a_n)} = \phi_{\gamma(b_n)}$. So, there exist real numbers a', b' with $a \leq a' < b' \leq b$ such that $t \mapsto \phi_{\gamma(t)}$ is injective on $[a', b']$ and satisfies $\phi_{\gamma(a')} = \phi_{\gamma(b')}$. Replacing γ by an equivalent transverse path, one can suppose that $\gamma(a') = \gamma(b')$. Let Γ' be the loop naturally defined by the closed path $\gamma|_{[a', b']}$. The set $U_{\Gamma'} = \bigcup_{t \in [a', b']} \phi_{\gamma(t)}$ is an open annulus and Γ' is a simple loop. As the path γ is a \mathcal{F} -bi-recurrent transverse path we have the following result. This lemma is contained in the proof of Proposition 2 from [LecT].

Lemma 3.2 ([LecT]). *Suppose that there exists $t < a'$ such that $\gamma(t) \notin U_{\Gamma'}$. Then there exists $t' \in \mathbb{R}$ with $b' < t'$ such that $\gamma(t)$ and $\gamma(t')$ are in the same connected component of the complement of $U_{\Gamma'}$. Moreover $\gamma|_{[t, t']}$ has a \mathcal{F} -transverse self-intersection.*

Proof. See the proof of Proposition 2 from [LecT]. ■

In the sequel, we assume, as in the previous subsection, that f is a homeomorphism of \mathbb{A} that is isotopic to the identity and preserves a Borel probability measure of full support, and that I is a maximal identity isotopy of f . We write \tilde{I} for the lifted isotopy of I and \tilde{f} for the lift of f associated to I . This isotopy is a maximal identity isotopy of \tilde{f} . We suppose that \mathcal{F} is an oriented singular foliation with $\text{dom}(\mathcal{F}) = \text{dom}(I)$ which is transverse to I and we write $\tilde{\mathcal{F}}$ for its lift to $\tilde{\mathbb{A}}$, which is transverse to \tilde{I} . We coming by the following result.

Lemma 3.3. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path and let $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ be a lift of γ to $\tilde{\mathbb{A}}$. Suppose that there exists a non-zero integer j such that $\tilde{\gamma}$ and $\tilde{\gamma} + (j, 0)$ intersect $\tilde{\mathcal{F}}$ -transversally. Then condition (i) or (ii) of Proposition 3.1 is satisfied.*

Proof. By density of bi-recurrent points of f and Lemma 2.5 we can suppose that γ is equivalent to a subpath of the whole transverse trajectory of a bi-recurrent point. Since this whole transverse trajectory has a \mathcal{F} -transverse self-intersection (by hypothesis), by Lemma 2.11, there exists a linearly admissible transverse loop Γ' with a \mathcal{F} -transverse self-intersection, such that γ is equivalent to subpaths of the natural lift of Γ' . We note that Γ' satisfies either condition (i) or (ii) of Proposition 3.1. ■

From Lemmas 3.2 and 3.3 we deduce the following result.

Lemma 3.4. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path. Suppose that there are real numbers $a < a' < b' < b$ such that $\gamma(a') = \gamma(b')$ and $t \mapsto$*

$\phi_{\gamma(t)}$ is injective on $[a', b']$. Let $U_{\Gamma'}$ be the open annulus associated to the loop naturally defined by the closed path $\gamma|_{[a', b']}$. Suppose furthermore that $\gamma(a)$ and $\gamma(b)$ belong to the same connected component of the complement of $U_{\Gamma'}$. Suppose that $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ is a lift of γ to $\tilde{\mathbb{A}}$ that has no $\tilde{\mathcal{F}}$ -transverse self-intersection. Then condition (i) or (ii) of Proposition 3.1 is satisfied.

Proof. By density of bi-recurrent points of f and Lemma 2.5 we can suppose that γ is equivalent to a subpath of the whole transverse trajectory of a bi-recurrent point. Since $\gamma(a)$ and $\gamma(b)$ belong to the same connected component of the complement of $U_{\Gamma'}$ we know, by Lemma 3.2, that the path γ has a \mathcal{F} -transverse self-intersection. Since $\tilde{\gamma}$ has no $\tilde{\mathcal{F}}$ -transverse self-intersection, there exists a non-zero integer j such that $\tilde{\gamma}$ and $\tilde{\gamma} + (j, 0)$ intersect $\tilde{\mathcal{F}}$ -transversally. Hence from Lemma 3.3, we know that condition (i) or (ii) of Proposition 3.1 is satisfied. This completes the proof of the lemma. ■

Lemma 3.5. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path and let $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ be a lift of γ . Suppose that there exist a leaf $\check{\phi}$ of $\tilde{\mathcal{F}}$ and three distinct integers j_i , $1 \leq i \leq 3$, such that $\tilde{\gamma}$ crosses each $\check{\phi} + (j_i, 0)$. Then one of conditions of Proposition 3.1 is satisfied.*

Proof. By density of the set of bi-recurrent points of f and Lemma 2.5 we can suppose that γ is equivalent to a subpath of γ' , the whole transverse trajectory of a bi-recurrent point. Since the lift $\tilde{\gamma}'$ of γ' that contains a subpath equivalent to $\tilde{\gamma}$ crosses each $\check{\phi} + (j_i, 0)$, $1 \leq i \leq 3$, it is sufficient to consider the case where γ' has a \mathcal{F} -transverse self-intersection. Otherwise γ' satisfies condition (iii) of Proposition 3.1. Hence, by Lemma 2.11, there exists a linearly admissible transverse loop Γ'' with a \mathcal{F} -transverse self-intersection such that γ is equivalent to subpaths of the natural lift of Γ'' . Write γ'' for the natural lift of Γ'' and for $\tilde{\gamma}''$ the lift of γ'' that contains a subpath equivalent to $\tilde{\gamma}$. We can suppose that $\tilde{\gamma}''$ is also a loop $\tilde{\Gamma}''$, otherwise Γ'' satisfies condition (i) of Proposition 3.1. In this case $\tilde{\Gamma}''$ is a $\tilde{\mathcal{F}}$ -recurrent transverse path that crosses each $\check{\phi} + (j_i, 0)$, $1 \leq i \leq 3$. Hence we can prove that there exist $i \neq i'$ such that $\tilde{\Gamma}'' - (j_i, 0)$ and $\tilde{\Gamma}'' - (j_{i'}, 0)$ intersect $\tilde{\mathcal{F}}$ -transversally (see the proof of Proposition 43 from [LecT]). This implies that $\tilde{\Gamma}''$ and $\tilde{\Gamma}'' + (j, 0)$ intersect $\tilde{\mathcal{F}}$ -transversally, where $j = j_i - j_{i'}$. Hence Γ'' satisfies condition (ii) of Proposition 3.1. This completes the proof. ■

Corollary 3.6. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path and let $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ be a lift of γ . Suppose that there exists an integer j with $|j| \geq 2$ such that $\phi_{\tilde{\gamma}(b)} = \phi_{\tilde{\gamma}(a)} + (j, 0)$. Then one of conditions of Proposition 3.1 is satisfied.*

Proof. We will write $\check{\phi}$ by the leaf $\phi_{\tilde{\gamma}(a)}$ of $\tilde{\mathcal{F}}$. By Lemma 2.9, there exists an admissible $\tilde{\mathcal{F}}$ -transverse path $\tilde{\gamma}' : [a, b] \rightarrow \tilde{\mathbb{A}}$ such that $\tilde{\gamma}'$ has no $\tilde{\mathcal{F}}$ -transverse self-intersection and $\phi_{\tilde{\gamma}'(a)} = \check{\phi}$, $\phi_{\tilde{\gamma}'(b)} = \check{\phi} + (j, 0)$. We will suppose that $j \geq 2$, the other case is proved similarly. By Lemma 3.5, we can suppose that for every $i \in \{1, \dots, j-1\}$ we have that $\tilde{\gamma}'$ does not meet $\check{\phi} + (i, 0)$. Let us fix

$i \in \{1, \dots, j-1\}$ and consider

$$a'_0 := \max \left\{ t \in [a, b] : \tilde{\gamma}'(t) \in \bigcup_{n \in \mathbb{N}} (\check{\phi} + (i - n, 0)) \right\},$$

$$b'_0 := \min \left\{ t \in [a'_0, b] : \tilde{\gamma}'(t) \in \bigcup_{n \in \mathbb{N}} (\check{\phi} + (i + n, 0)) \right\},$$

and let $\tilde{\gamma}'_0 = \tilde{\gamma}'|_{[a'_0, b'_0]}$. By Proposition 2.15 we know that $\tilde{\gamma}'_0$ meets $\tilde{\gamma}'_0 + (1, 0)$. Hence $\tilde{\gamma}'_0$ projects onto an admissible \mathcal{F} -transverse path γ'_0 which there exist real numbers $a'_0 < a''_0 < b''_0 < b'_0$ such that $\gamma'_0(a''_0) = \gamma'_0(b''_0)$ and $t \mapsto \phi_{\gamma'_0(t)}$ is injective on $[a''_0, b''_0]$. Let $U_{\Gamma''_0}$ be the open annulus associated to the loop naturally defined by the closed path $\gamma'_0|_{[a''_0, b''_0]}$. We note that by construction $\gamma'(a'_0)$ and $\gamma'(b'_0)$ belong to the same leaf (the projection of $\check{\phi}$) and it does not belong to the annulus $U_{\Gamma''_0}$. We deduce the corollary from Lemma 3.4. \blacksquare

We deduce the following corollary.

Corollary 3.7. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path and let $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ be a lift of γ . Suppose that there exist a leaf $\check{\phi}$ of $\tilde{\mathcal{F}}$ and an integer j with $|j| \geq 2$, such that $\tilde{\gamma}$ crosses both $\check{\phi}$ and $\check{\phi} + (j, 0)$. Then one of conditions of Proposition 3.1 is satisfied.*

Proof. Since in the proof of Lemma 3.5 we can obtain a linearly admissible transverse loop Γ'' with a \mathcal{F} -transverse self-intersection such that γ is equivalent to subpaths of the natural lift of Γ'' . Consider real numbers $a < a' < b' < b$ such that $\phi_{\gamma(a')} = \check{\phi}$ and $\phi_{\gamma(b')} = \check{\phi} + (j, 0)$. Since Γ'' is linearly admissible there is an integer $n \geq 1$ such that $\gamma|_{[a', b']}$ is admissible of order $\leq n$, and so by Lemma 2.6 it is admissible of order n . The corollary follows from the previous corollary. \blacksquare

Finally we deduce the following corollary which will be used in the proof of Theorem A.

Corollary 3.8. *Let $\gamma : [a, b] \rightarrow \mathbb{A}$ be an admissible \mathcal{F} -transverse path and let $\delta : [0, 1] \rightarrow \mathbb{A}$ be a simple segment that joins $\phi_{\gamma(a)}$ to $\phi_{\gamma(b)}$ which does not meet $\phi_{\gamma(a)}$ and $\phi_{\gamma(b)}$ but at the ends. Let $\tilde{\gamma} : [a, b] \rightarrow \tilde{\mathbb{A}}$ be a lift of γ and let $\tilde{\delta} : [0, 1] \rightarrow \tilde{\mathbb{A}}$ be the lift of δ such that $\tilde{\delta}(0) \in \phi_{\tilde{\gamma}(a)}$. Assume that there exists an integer $j \geq 4$ such that $\tilde{\delta}(1) + (j, 0) \in \phi_{\tilde{\gamma}(b)}$. Suppose that there exist an admissible path $\tilde{\gamma}' : [a, b] \rightarrow \tilde{\mathbb{A}}$ which has no $\tilde{\mathcal{F}}$ -transverse self-intersection and $\phi_{\tilde{\gamma}'(a)} = \phi_{\tilde{\gamma}(a)}$, $\phi_{\tilde{\gamma}'(b)} = \phi_{\tilde{\gamma}(b)}$ and an integer $i \in \{2, \dots, j-2\}$ such that $\tilde{\gamma}'$ does not meet $\tilde{\delta} + (i, 0)$. Then either condition (i) or (ii) of Proposition 3.1 is satisfied.*

Proof. Let us consider δ' the union of the segment included in $\phi_{\gamma(a)}$ that joins $\gamma'(a)$ to $\delta(0)$, of δ and of the segment included in $\phi_{\gamma(b)}$ that joins $\delta(1)$ to $\gamma'(b)$ and let $\tilde{\delta}'$ be the lift of δ' containing $\tilde{\delta}$. We note that, by Corollary 3.7, $\tilde{\gamma}'$ does

not cross none $\phi_{\tilde{\gamma}(a)} + (i, 0)$ and $\phi_{\tilde{\gamma}(b)} + (i - j, 0)$, because $i \in \{2, \dots, j - 2\}$ and so it does not meet $\check{\delta}' + (i, 0)$. Let us consider

$$a'_0 := \max \left\{ t \in [a, b] : \tilde{\gamma}'(t) \in \bigcup_{n \in \mathbb{N}} (\check{\delta}' + (i - n, 0)) \right\},$$

$$b'_0 := \min \left\{ t \in [a'_0, b] : \tilde{\gamma}'(t) \in \bigcup_{n \in \mathbb{N}} (\check{\delta}' + (i + n, 0)) \right\},$$

and let $\tilde{\gamma}'_0 = \tilde{\gamma}'|_{[a'_0, b'_0]}$. By Proposition 2.15 we know that $\tilde{\gamma}'_0$ meets $\check{\gamma}'_0 + (1, 0)$. Hence $\tilde{\gamma}'_0$ projects onto an admissible \mathcal{F} -transverse path γ'_0 which there exist real numbers $a'_0 < a''_0 < b''_0 < b'_0$ such that $\gamma_0(a''_0) = \gamma_0(b''_0)$ and $t \mapsto \phi_{\gamma'_0(t)}$ is injective on $[a''_0, b''_0]$. Let $U_{\Gamma'_0}$ be the open annulus associated to the loop naturally defined by the closed path $\gamma'_0|_{[a''_0, b''_0]}$. Since by construction the path γ'_0 does not cross none $\phi_{\gamma(a)}$, δ and $\phi_{\gamma(b)}$, but at the ends, we deduce that the leaves $\phi_{\gamma'(a'_0)}$ and $\phi_{\gamma'(b'_0)}$ belong to the same connected component of $U_{\Gamma'_0}$. The corollary follows of Lemma 3.4. This completes the proof of the corollary. ■

3.2 Proof of Proposition 3.1

In this subsection we show Proposition 3.1. In the sequel, we assume that f is a homeomorphism of \mathbb{A} which is isotopic to the identity and preserves a Borel probability measure of full support, and that I is a maximal identity isotopy of f . We write \check{I} for the lifted isotopy of I and \check{f} for the lift of f associated to I , which has fixed points. This isotopy is a maximal identity isotopy of \check{f} . We suppose that \mathcal{F} is an oriented singular foliation on \mathbb{A} with $\text{dom}(\mathcal{F}) = \text{dom}(I)$ which is transverse to I and we write $\check{\mathcal{F}}$ for its lift to $\check{\mathbb{A}}$, which is transverse to \check{I} .

Let us suppose that condition (i) holds, i.e. there exist a linearly admissible transverse loop $\Gamma : \mathbb{T}^1 \rightarrow \mathbb{A}$ with a \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of the natural lift of Γ to $\check{\mathbb{A}}$, and a non-zero integer j such that for every $t \in \mathbb{R}$ we have $\tilde{\gamma}(t + 1) = \tilde{\gamma}(t) + (j, 0)$. Suppose that Γ satisfies property (Q_q) for some integer $q \geq 1$. By Proposition 2.10, we have that for every rational number $r/s \in (0, 1/q]$, written in an irreducible way, the loop Γ^r is associated to a periodic orbit of period s . In particular, the map $\check{z} \mapsto \check{f}^q(\check{z}) + (j, 0)$ or $\check{z} \mapsto \check{f}^q(\check{z}) - (j, 0)$ has a fixed point. Since \check{f} has fixed points and the rotation set of \check{f} is an interval (Theorem 2.12) the proof of Proposition 3.1 follows in the first case.

Let us suppose that condition (ii) holds, i.e. there exists a linearly admissible transverse loop $\Gamma : \mathbb{T}^1 \rightarrow \mathbb{A}$ with a \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of the natural lift of Γ to $\check{\mathbb{A}}$ and a non-zero integer j such that $\tilde{\gamma}$ is a loop $\check{\Gamma}$ and $\check{\Gamma}$ and $\check{\Gamma} + (j, 0)$ have a $\check{\mathcal{F}}$ -transverse self-intersection. Write $\tilde{\gamma}$ for the natural lift of $\check{\Gamma}$ and choose an integer L sufficient large, such that $\tilde{\gamma}|_{[0, L]}$ has a $\check{\mathcal{F}}$ -transverse intersection with $\tilde{\gamma}|_{[0, L]} + (j, 0)$ at $\tilde{\gamma}(t) = \tilde{\gamma}(s) + (j, 0)$ with $s < t$. The loop $\check{\Gamma}$

being linearly admissible, there exists an integer $q \geq 1$ such that $\tilde{\gamma}|_{[-L, 2L]}$ is admissible of order q . It follows from Lemmas 2.8 and 2.6 that for every integer $n \geq 1$, the paths

$$\prod_{i=0}^{n-1} (\tilde{\gamma}|_{[s-L, t+L]} + (ij, 0)) \quad \text{and} \quad \prod_{i=0}^{n-1} (\tilde{\gamma}|_{[t-L, s+L]} - (ij, 0)),$$

are admissible of order nq , and both have $\tilde{\mathcal{F}}$ -transverse self-intersection. Therefore the paths $\tilde{\gamma}|_{[s-L, t+L]}$ and $\tilde{\gamma}|_{[t-L, s+L]}$ project onto closed paths of \mathbb{A} and the two loops naturally defined have \mathcal{F} -transverse self-intersection and are linearly admissible. We conclude as in the first case. This completes the proof of Proposition 3.1 in the second case.

Let us suppose that condition (iii) holds, i.e. there exist an admissible \mathcal{F} -bi-recurrent path $\gamma : \mathbb{R} \rightarrow \mathbb{A}$ which has no \mathcal{F} -transverse self-intersection, a lift $\tilde{\gamma}$ of γ to $\tilde{\mathbb{A}}$, a leaf $\tilde{\phi}$ of $\tilde{\mathcal{F}}$ and a non-zero integer j such that $\tilde{\gamma}$ crosses both $\tilde{\phi}$ and $\tilde{\phi} + (j, 0)$. By Proposition 2.1 the path γ is equivalent to the natural lift of a transverse simple loop Γ , denoted still γ . Consider the set $U_\Gamma = \cup_{t \in \mathbb{R}} \phi_{\gamma(t)}$ which is an essential open annulus in \mathbb{A} , because $\tilde{\gamma}$ crosses both $\tilde{\phi}$ and $\tilde{\phi} + (j, 0)$. Let \tilde{U}_Γ be a lift of U_Γ to $\tilde{\mathbb{A}}$. The previous cases and the following result permits us to conclude the existence of periodic point of arbitrarily large prime period for f , in the case that there is a f -recurrent point whose whole transverse trajectory and Γ intersect \mathcal{F} -transversally.

Lemma 3.9. *Let γ' be the whole transverse trajectory of a recurrent point. Suppose that γ' and Γ have a \mathcal{F} -transverse intersection. Then there exists a linearly admissible loop that satisfies either condition (i) or (ii) of Proposition 3.1.*

Proof. Let $\tilde{\gamma}$ be a lift of γ and suppose that for every real number t we have $\tilde{\gamma}(t+1) = \tilde{\gamma}(t) + (1, 0)$. The path γ' being \mathcal{F} -recurrent and having \mathcal{F} -transverse intersection with γ , one can find real numbers

$$s_2 \text{ and } a_1 < t_1 \leq t'_1 < b_1,$$

an integer $k' \geq 0$, and a lift $\tilde{\gamma}'$ of γ' such that:

- $\tilde{\gamma}'|_{[t_1, t'_1]}$ is equivalent to $\tilde{\gamma}|_{[s_2, s_2+k']}$;
- $\tilde{\gamma}'|_{(a_1, t_1)}$ and $\tilde{\gamma}'|_{(t'_1, b_1)}$ are included in \tilde{U}_Γ but that do not meet $\phi_{\tilde{\gamma}(s_2-1)}$ and $\phi_{\tilde{\gamma}(s_2+k'+1)}$ respectively;
- $\tilde{\gamma}'(a_1)$ and $\tilde{\gamma}'(b_1)$ do not belong to \tilde{U}_Γ and $\tilde{\gamma}'(a_1)$ and $\tilde{\gamma}'(b_1)$ belong to different connected components of the complement of \tilde{U}_Γ .

Hence as the path γ' is \mathcal{F} -recurrent and the complement of the set U_Γ saturated, one can find real numbers $b_1 \leq a_3 < b_3$, an integer $k'' \geq k'$, and an lift $\tilde{\gamma}''$ of γ' such that:

- $\tilde{\gamma}''(b_3)$ belongs to the same connected component of the complement of \tilde{U}_Γ than $\tilde{\gamma}'(a_1)$;
- $\tilde{\gamma}''|_{[b_1, a_3]}$ does not meet this component;
- $\tilde{\gamma}''|_{(a_3, b_3)}$ is included in \tilde{U}_Γ but it is between $\phi_{\tilde{\gamma}(s_2+k'+1)}$ and $\phi_{\tilde{\gamma}(s_2+k''+2)}$;
- $\tilde{\gamma}''(a_3)$ does not belong to \tilde{U}_Γ .

Let fix $s_3 \in (a_3, b_3)$. There exists $t_2 > s_2 + k' + 1$ such that $\phi_{\tilde{\gamma}(t_2)} = \phi_{\tilde{\gamma}''(s_3)}$. Observe now that, by Lemma 2.2, $\tilde{\gamma}'|_{[a_1, b_1]}$ and $\tilde{\gamma}|_{[s_2-1, t_2]}$ intersect $\tilde{\mathcal{F}}$ -transversally at $\tilde{\gamma}'(t_1) = \tilde{\gamma}(s_2)$ and $\tilde{\gamma}|_{[s_2, s_2+k''+1]}$ and $\tilde{\gamma}''|_{[a_3, b_3]}$ intersect $\tilde{\mathcal{F}}$ -transversally at $\tilde{\gamma}(t_2) = \tilde{\gamma}''(s_3)$. Hence by Lemma 2.8, one has that the path

$$\tilde{\gamma}^* = \tilde{\gamma}'|_{[a_1, t_1]} \tilde{\gamma}|_{[s_2, t_2]} \tilde{\gamma}''|_{[s_3, b_3]}$$

is a subpath of an admissible path. Moreover, we note that there exist real numbers $a < s < t < b$ such that:

- $\tilde{\gamma}^*|_{(s, t)}$ is equivalent to $\tilde{\gamma}|_{(s_2, s_2+k'')}$;
- $\tilde{\gamma}^*|_{(a, s)}$ is included in \tilde{U}_Γ but it does not meet $\phi_{\tilde{\gamma}(s_2-1)}$;
- $\tilde{\gamma}^*|_{(t, b)}$ is included in \tilde{U}_Γ but it does not meet $\phi_{\tilde{\gamma}(s_2+k''+1)}$;
- $\tilde{\gamma}^*(a)$ and $\tilde{\gamma}^*(b)$ do not belong to \tilde{U}_Γ and $\tilde{\gamma}^*(a)$ and $\tilde{\gamma}^*(b)$ belong to the same connected component of the complement of \tilde{U}_Γ .

This implies that the paths $\tilde{\gamma}^*|_{[a, t]}$ and $\tilde{\gamma}^*|_{[s, b]} - (k'', 0)$ have a $\tilde{\mathcal{F}}$ -transverse intersection at $\phi_{\tilde{\gamma}(s_2)}$. It follows from Lemma 3.3 that either condition (i) or (ii) of the Proposition 3.1 is satisfied. This completes the proof of the lemma. ■

Let us suppose now that there is no a f -recurrent point whose whole transverse trajectory and Γ intersect \mathcal{F} -transversally. We denote $\text{Rec}(f)_\Gamma$ the set of bi-recurrent points of f whose whole transverse trajectory is equivalent to the natural lift of Γ . Define

$$A_\Gamma := \text{Int}(\overline{\text{Rec}(f)_\Gamma}).$$

We can state the following proposition.

Proposition 3.10 (Proposition 54, [LecT]). *The set A_Γ is a fixed point free f -invariant open annulus which is essential in U_Γ . Moreover A_Γ is essential in \mathbb{A} .*

Since A_Γ is essential in \mathbb{A} , we have that the rotation set of \tilde{f} restrict to the open annulus A_Γ is contained in the rotation set of \tilde{f} . Since the rotation set of \tilde{f} is an interval, Theorem 2.12, we again deduce the existence of non-contractible periodic points of arbitrarily large prime period of the following lemma. We recall that \tilde{f} has fixed points.

Lemma 3.11. *The rotation set of \check{f} restrict to the open annulus A_Γ contains non-zero rotation number.*

Proof. It follows of the fact that f restrict to the open annulus A_Γ is fixed point free and preserves a Borel probability measure (see Lemma 2.13). ■

This completes the proof of Proposition 3.1.

3.3 End of the proof of Theorem B and proof of Theorem C

End of the proof of Theorem B. Suppose that Assertion (ii) is not hold. It is there exists a recurrent point $z_0 \in \mathbb{A}$ such that for every neighborhood V of z_0 , \check{V} lift of V , and \check{z}_0 the lift of z_0 contained in \check{V} there exists an integer $n \geq 1$ such that $f^n(z_0) \in V$, but $\check{f}^n(\check{z}_0) \in \check{V} + (j, 0)$ for some non-zero integer j . On the other hand, by Lemma 2.5, we can find a neighborhood W of z_0 such that for every $z \in W$ the path $I_{\check{F}}^2(f^{-1}(z))$ crosses the leaf ϕ_{z_0} . Let \check{W} be a lift of W to $\check{\mathbb{A}}$ containing \check{z}_0 . Therefore Corollary 3.7 permits to conclude that for every neighborhood $\check{V} \subset \check{W}$ of \check{z}_0 there is an integer $n \geq 1$ such that $f^n(z_0) \in V$, but $\check{f}^n(\check{z}_0) \in \check{V} + (1, 0)$. Since z_0 is a recurrent point (by f) there exists a sequence $(m_k)_{k \in \mathbb{N}}$ of integers which goes to $+\infty$ such that the sequence $(f^{m_k}(z_0))_{k \in \mathbb{N}}$ converges to z_0 . We claim that there exists an sequence $(m'_k)_{k \in \mathbb{N}}$ of integers which goes to $+\infty$ such that the sequence $(\check{f}^{m'_k}(\check{z}_0))_{k \in \mathbb{N}}$ converges to $\check{z}_0 + (1, 0)$. Indeed, we can suppose that $(\check{f}^{m_k}(\check{z}_0))_{k \in \mathbb{N}}$ converges to \check{z}_0 , otherwise we are done. Let $k \geq 1$ be an integer, and fix a small neighborhood \check{V} of \check{z}_0 of diameter smaller than $1/k$ and an integer $n_k \geq 1$ such that $\check{f}^{n_k}(\check{z}_0) \in \check{W} + (1, 0)$. We note that by continuity of \check{f}^{n_k} at \check{z}_0 we can find an integer $j_k \in \mathbb{N}$ such that $\check{f}^{n_k+m_{j_k}}(\check{z}_0)$ belongs to $\check{W} + (1, 0)$. Since the integer k can be chosen arbitrarily large, the sequence $(m'_k)_{k \in \mathbb{N}}$, where $m'_k = n_k + m_{j_k}$, is such that $(\check{f}^{m'_k}(\check{z}_0))_{k \in \mathbb{N}}$ converges to $\check{z}_0 + (1, 0)$. Now fix us an integer $k \geq 1$. By continuity of $\check{f}^{m'_k}$ at $\check{z}_0 + (1, 0)$ and the fact that \check{f} commutes with the translation $\check{z} \mapsto \check{z} + (1, 0)$, we can find an integer $j \in \mathbb{N}$ such that $\check{f}^{m'_k+m'_j}(\check{z}_0)$ belongs to $\check{W} + (2, 0)$. Hence the transverse path $I_{\check{F}}^{m'_k+m'_j+1}(\check{z}_0)$ crosses each $\phi_{\check{z}_0} + (i, 0)$, $0 \leq i \leq 2$. Therefore Lemma 3.5 permits to conclude that one of conditions of Proposition 3.1 is satisfied. We conclude using Proposition 3.1 that Assertion (i) of Theorem B holds. This completes the proof of Theorem B. ■

Proof of Theorem C. Since f is an irrotational homeomorphism which preserves a Borel probability measure, we know that the set of bi-recurrent points of f is dense in \mathbb{A} and the irrotational lift \check{f} of f has fixed points (Lemma 2.13) and it does not have non-contractible periodic points. Hence by Theorem B every bi-recurrent point of f lifts to a bi-recurrent point of \check{f} , and so the set of \check{f} -bi-recurrent points is dense in $\check{\mathbb{A}}$. This implies that for every open set \check{U} of $\check{\mathbb{A}}$ there exist a point $\check{z} \in \check{U}$ and an integer $n \geq 1$, such that $\check{f}^n(\check{z}) \in \check{U}$, that is \check{f} is non-wandering. This completes the proof of Theorem C. ■

4 Proof of Theorem A

In this section we will prove Theorem A. Let f be a homeomorphism of \mathbb{A} which is isotopic to the identity. We will suppose that f preserves a Borel probability measure of full support, and so the set of bi-recurrent points is dense in \mathbb{A} . Assume that the connected components of the set of fixed points of f are all compact. Let \check{f} be a lift of f to $\check{\mathbb{A}}$. Assume that \check{f} has fixed points and that there exists an open topological disk $U \subset \mathbb{A}$ such that the set of fixed points of \check{f} projects into U . We will suppose that Case (2) of Theorem A does not hold, i.e. considering f^{-1} instead of f (if necessary) we will suppose that

- (H_1) there exist a compact set K_0 of \mathbb{A} , a sequence of points $(z_l)_{l \in \mathbb{N}}$ in K_0 , and a sequence of integers $(n_l)_{l \in \mathbb{N}}$ which goes to $+\infty$ such that the sequence $(f^{n_l}(z_l))_{l \in \mathbb{N}}$ is in K_0 and

$$p_1(\check{f}^{n_l}(\check{z}_l)) - p_1(\check{z}_l) \geq M_l,$$

where $\check{z}_l \in \check{\pi}^{-1}(z_l)$ and the sequence $(M_l)_{l \in \mathbb{N}}$ tends to $+\infty$ as l goes to $+\infty$.

It follows from Theorem C that:

- (H_2) the set of bi-recurrent points of \check{f} is dense in $\check{\mathbb{A}}$.

Let I' be an identity isotopy of f , such that its lift to $\check{\mathbb{A}}$, \check{I}' , is an identity isotopy of \check{f} . By Theorem 2.3 one can find a maximal singular isotopy $I = (f_t)_{t \in [0,1]}$ larger than I' . It can be lifted to an isotopy $\check{I} = (\check{f}_t)_{t \in [0,1]}$ with $\text{dom}(\check{I}) = \check{\pi}^{-1}(\text{dom}(I))$. This isotopy is a maximal singular isotopy of \check{f} larger than \check{I}' . By Theorem 2.4 one can find an oriented singular foliation \mathcal{F} on \mathbb{A} which is transverse to I , its lift to $\check{\mathbb{A}}$, denoted by $\check{\mathcal{F}}$, is transverse to \check{I} . The following lemma is a consequence of Proposition 43 from [LecT].

Lemma 4.1. *Let $\check{\gamma} : [a, b] \rightarrow \check{\mathbb{A}}$ be an admissible $\check{\mathcal{F}}$ -transverse path. Suppose that there exist a leaf $\check{\phi}$ of $\check{\mathcal{F}}$ and three distinct integers j_i , $1 \leq i \leq 3$, such that $\check{\gamma}$ crosses each $\check{\phi} + (j_i, 0)$. Then there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in [-1/q, 1/q]$, the map $\check{z} \mapsto \check{f}^s(\check{z}) + (r, 0)$ has a fixed point. In particular, f has non-contractible periodic points of arbitrarily large prime period.*

Proof. Since the set of bi-recurrent points of \check{f} is dense in $\check{\mathbb{A}}$ (Hypothesis (H_2)), Lemma 2.5, Proposition 2.1 and Lemma 2.11 permit to find a linearly admissible loop $\check{\Gamma}$ in $\check{\mathbb{A}}$ that crosses each $\check{\phi} + (j_i, 0)$, $1 \leq i \leq 3$. Hence we can prove that there exist $i \neq i'$ such that $\check{\Gamma} - (j_i, 0)$ and $\check{\Gamma} - (j_{i'}, 0)$ intersect $\check{\mathcal{F}}$ -transversally (see proof of Proposition 43 from [LecT]). This implies that $\check{\Gamma}$ and $\check{\Gamma} + (j, 0)$ intersect $\check{\mathcal{F}}$ -transversally, where $j = j_i - j_{i'}$. The proof follows as in the proof of condition (ii) of Proposition 3.1. \blacksquare

Considering subsequences we can suppose that the sequences $(z_l)_{l \in \mathbb{N}}$ and $(f^{n_l}(z_l))_{l \in \mathbb{N}}$ converge in K_0 to the limits denoted by z_∞ and z'_∞ respectively.

Let us fix two distinct singularities x_∞ and x'_∞ of \mathcal{F} which can be joining by simple paths to z_∞ and z'_∞ respectively (if necessary). For every integer $l \geq 1$ consider a simple path δ_l joining x_∞ to x'_∞ which passes by z_l and $f^{n_l}(z_l)$ such that their union K is contained in a closed topological disk of \mathbb{A} (see Figure 3).

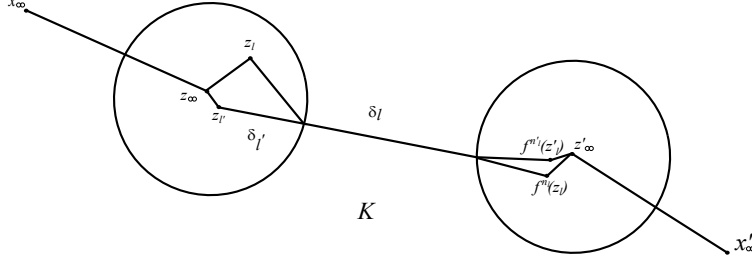

Figure 3: The set K .

Let \check{K} be a lift of K to $\check{\mathbb{A}}$. For every $l \in \mathbb{N}$, we consider the path transverse $\check{\gamma}_l = I_{\check{\mathcal{F}}}^{n_l}(\check{z}_l)$, where \check{z}_l is the lift of z_l contained in \check{K} and let $\check{\delta}_l$ be the lift of δ_l containing \check{z}_l . By Lemma 2.9, there exists a transverse path $\check{\gamma}'_l = I_{\check{\mathcal{F}}}^{n_l}(\check{z}'_l)$ such that $\check{\gamma}'_l$ has no $\check{\mathcal{F}}$ -transverse self-intersection and $\check{z}'_l \in \phi_{\check{z}_l}$, $\check{f}^{n_l}(\check{z}'_l) \in \phi_{\check{f}^{n_l}(\check{z}_l)}$. Given an integer $l \in \mathbb{N}$, let $j_l \geq 1$ such that $\check{f}^{n_l}(\check{z}_l) \in (\check{\delta}_l + (j_l, 0))$. We have the following result.

Lemma 4.2. *For every large l such that $j_l \geq 4$, we have*

- (a) *for every $i \in \{2, \dots, j_l - 2\}$, the path $\check{\gamma}'_l$ meets $\check{\delta}_l + (i, 0)$, or*
- (b) *there exists an integer $q \geq 1$ such that, for every irreducible rational number $r/s \in [-1/q, 1/q]$, the map $\check{z} \mapsto \check{f}^s(\check{z}) + (r, 0)$ has a fixed point. In particular, f has non-contractible periodic points of arbitrarily large prime period.*

Proof. Suppose that Assertion (a) does not hold, that is there exists an integer $i \in \{2, \dots, j_l - 2\}$ such that the path $\check{\gamma}'_l$ does not meet $\check{\delta}_l + (i, 0)$. It follows of Corollary 3.8 that one of conditions of Proposition 3.1 is satisfied, and so there exists an integer $q \geq 1$ such for, every irreducible rational number $r/s \in (0, 1/q]$, the map $\check{z} \mapsto \check{f}^s(\check{z}) + (r, 0)$ or $\check{z} \mapsto \check{f}^s(\check{z}) - (r, 0)$ has a fixed point. Let us fix such a fixed point \check{z} . Then its whole transverse trajectory crosses infinitely many translates of $\phi_{\check{z}}$. By Lemma 4.1 it follows that Assertion (b) holds. This completes the proof of the lemma. \blacksquare

From now on we will suppose that Assertion (a) of the previous lemma holds. Otherwise the proof of Theorem A finishes. We have the following result.

Lemma 4.3. *There exists a neighborhood $V_{\check{K}}$ of \check{K} in $\check{\mathbb{A}}$ such that for every integer $j \in \{2, \dots, j_l - 2\}$ there exists an integer $i_j \in \{0, \dots, n_l\}$ such that $\check{f}^{i_j}(\check{z}'_l)$ and $\check{f}^{i_j+1}(\check{z}'_l)$ belong to $V_{\check{K}} + (j, 0)$.*

Proof. Let $j \in \{2, \dots, j_l - 2\}$. We are assuming that $\check{\gamma}'_l$ meets $\check{\delta}_l + (j, 0)$. Since $\check{\gamma}'_l$ is homotopic, relative to the endpoints, to the trajectory $I^{n_l}(\check{z}'_l)$ in $\check{\mathbb{A}} \setminus \text{Sing}(\check{\mathcal{F}})$, we deduce that the trajectory $I^{n_l}(\check{z}'_l)$ intersects $\check{\delta}_l + (j, 0) \subset \check{K} + (j, 0)$ too. This implies that there is at least an integer $i_j \in \{0, \dots, n_l\}$ such that the trajectory of the point $\check{f}^{i_j}(\check{z}'_l)$ which is the path $I(\check{f}^{i_j}(\check{z}'_l)) : t \mapsto \check{f}_t(\check{f}^{i_j}(\check{z}'_l))$ intersects $\check{K} + (j, 0)$. Consider

$$M_{\check{K}} := \sup\{\|\check{f}_t^{-1}(\check{z}') - \check{f}_{t'}^{-1}(\check{z}')\| : \check{z}' \in \check{K}, t, t' \in [0, 1]\},$$

where $\|\cdot\|$ denotes the Euclidean norm. It is easy to prove that $\check{f}^{i_j}(\check{z}'_l)$ and $\check{f}^{i_j+1}(\check{z}'_l)$ belong to $V_{\check{K}} + (j, 0)$ where

$$V_{\check{K}} := d(\check{K}, M_{\check{K}}) := \{w \in \mathbb{R}^2 : \|w - w'\| < M_{\check{K}} \text{ for some } w' \in \check{K}\}.$$

This completes the proof of the lemma (see Figure 4). ■

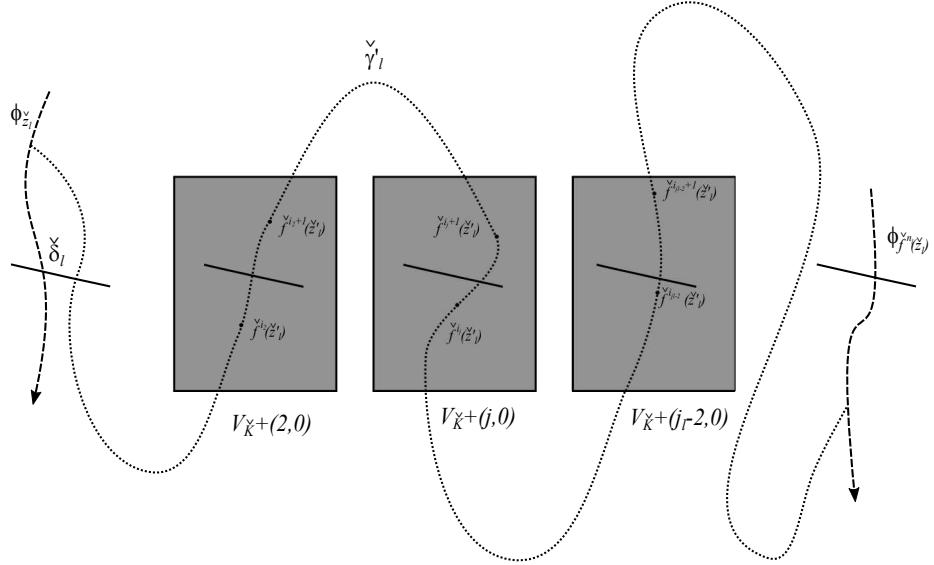

Figure 4: Proof of Lemma 4.3.

From our suppositions, the set of fixed points of \check{f} is not empty and it projects into an open topological disk U of \mathbb{A} . We have the following result.

Lemma 4.4. *Let \check{U} be a connected component of $\pi^{-1}(U)$. Let \mathcal{A} be an essential compact annulus of \mathbb{A} and let $\check{\mathcal{A}}$ be a lift of \mathcal{A} to $\check{\mathbb{A}}$. Then the diameter of the set $\check{U} \cap \check{\mathcal{A}} \cap \text{Sing}(\check{\mathcal{F}})$ is bounded.*

Proof. Suppose by contradiction that it is unbounded, i.e. there exists a sequence $(\check{x}_n)_{n \in \mathbb{N}}$ of singularities of $\check{\mathcal{F}}$ in $\check{U} \cap \check{\mathcal{A}}$ such that the sequence $(p_1(\check{x}_n))_{n \in \mathbb{N}}$ is unbounded. By compactness of $\text{Sing}(\mathcal{F}) \cap \mathcal{A}$, we can suppose that the sequence $(\tilde{\pi}(\check{x}_n))_{n \in \mathbb{N}}$ converges to x in $\text{Sing}(\mathcal{F}) \cap \mathcal{A}$. Since the open disk U contains all singularities of \mathcal{F} , we have that x is in U . Let \check{x} be the lift of x contained in \check{U} . Since \check{U} is an open disk in $\check{\mathbb{A}}$, we can find a small bounded ball D contained in \check{U} and containing \check{x} . Therefore there are a non-zero integer j and a large enough integer n such that $\check{x}_n + (j, 0)$ is in $D \subset \check{U}$. This implies that \check{x}_n is in $(\check{U} - (j, 0)) \cap \check{U}$ with $j \neq 0$. Since \check{U} is arcwise-connected, this contradicts the fact that $U = \tilde{\pi}(\check{U})$ is an open topological disk in the open annulus \mathbb{A} . This completes the proof of the lemma. \blacksquare

From our suppositions, the connected components of the set of fixed points of f are all compact. Hence we can consider two essential compact annuli \mathcal{A}_N and \mathcal{A}_S in \mathbb{A} which do not contain singularities of \mathcal{F} , such that the essential compact annulus \mathcal{A}' between the annuli \mathcal{A}_N and \mathcal{A}_S contains the set $\tilde{\pi}(V_{\check{K}})$, where $V_{\check{K}}$ is the neighborhood of \check{K} provided by Lemma 4.3, and satisfying

$$f^{-1}(\mathcal{A}') \cup f(\mathcal{A}') \subset \mathcal{A} = \mathcal{A}_N \cup \mathcal{A}' \cup \mathcal{A}_S. \quad (1)$$

Let $\check{\mathcal{A}}_N$, $\check{\mathcal{A}}_S$ and $\check{\mathcal{A}}'$ be the lifts of \mathcal{A}_N , \mathcal{A}_S and \mathcal{A}' respectively and let $\check{\mathcal{A}} = \check{\mathcal{A}}_N \cup \check{\mathcal{A}}' \cup \check{\mathcal{A}}_S$. From the previous lemma, one can find an open neighborhood $V \subset U$ of $\text{Sing}(\mathcal{F})$ such that the diameter of $\check{V} \cap \check{\mathcal{A}} \cap \text{Sing}(\check{\mathcal{F}})$ is bounded and such that for every point $\check{z} \in \tilde{\pi}^{-1}(V)$, the points \check{z} and $\check{f}(\check{z})$ belong to the same connected component of $\tilde{\pi}^{-1}(U)$. One knows that for every point $z \in (\mathcal{A}' \setminus V) \cup \mathcal{A}_N \cup \mathcal{A}_S$, there exists a small open disk $O \subset \text{dom}(\mathcal{F})$ containing z such that for every $z' \in O$ the path $I_{\mathcal{F}}^2(f^{-1}(z'))$ crosses the leaf ϕ_z . By compactness of $(\mathcal{A}' \setminus V) \cup \mathcal{A}_N \cup \mathcal{A}_S$, one can cover this set by a finite family $(O_i)_{1 \leq i \leq r}$ with $r = r' + r_N + r_S$, where $(O_i)_{1 \leq i \leq r'}$ is a cover of $\mathcal{A}' \setminus V$, $(O_i)_{r'+1 \leq i \leq r'+r_N}$ is a cover of \mathcal{A}_N and $(O_i)_{r'+r_N+1 \leq i \leq r'+r_N+r_S}$ is a cover of \mathcal{A}_S . One can construct a partition $(X_i)_{1 \leq i \leq r}$ with $r = r' + r_N + r_S$ of $(\mathcal{A}' \setminus V) \cup \mathcal{A}_N \cup \mathcal{A}_S$ such that, for every $i \in \{1, \dots, r\}$ we have $X_i \subset O_i$. We have a unique partition $(\check{X}_\alpha)_{\alpha \in \check{\mathcal{A}}}$ of $\check{\mathcal{A}}$ such that, either \check{X}_α is contained in a connected component of $\tilde{\pi}^{-1}(U)$ and projects onto V , there exists $i \in \{1, \dots, r\}$ such that \check{X}_α is contained in a connected component of $\tilde{\pi}^{-1}(O_i)$, and projects onto X_i , or \check{X}_α is one connected component of $\check{\mathcal{A}} \setminus \check{\mathcal{A}}$. We write $\alpha(\check{z}) = \alpha$, if $\check{z} \in \check{X}_\alpha$. Let us define

$$M_{\mathcal{A}}^0 = \max_{\check{z} \in \check{\mathcal{A}}} |p_1(\check{f}(\check{z})) - p_1(\check{z})| \quad \text{and} \quad M_{\mathcal{A}}^1 = \max_{\alpha \in \mathcal{A}'} \text{diam}(p_1(\check{X}_\alpha)),$$

where \check{X}_α with $\alpha \in \mathcal{A}'$ projects onto \mathcal{A} .

Let us fix $\check{z} \in \tilde{\pi}^{-1}(\mathcal{A}')$, an integer $m \geq 1$ such that $\check{f}^m(\check{z}) \in \tilde{\pi}^{-1}(\mathcal{A}')$, and define a sequence $m_0 < m_1 < \dots < m_s$ in the following inductive way:

$$m_0 = 0, \quad m_{l+1} = 1 + \sup\{k \in \{m_l, \dots, m-1\} \mid \alpha(\check{f}^k(\check{z})) = \alpha(\check{f}^{m_l}(\check{z}))\}, \quad m_s = m.$$

We have the following facts:

- (i) for every $l \in \{1, \dots, s-1\}$ at least one the sets $\check{X}_{\alpha(\check{f}^{m_l}(\check{z}))}$ and $\check{X}_{\alpha(\check{f}^{m_{l+1}}(\check{z}))}$ do not project on $V \cap \mathcal{A}'$;
- (ii) If $\check{X}_{\alpha(\check{f}^{m_l}(\check{z}))}$ and $\check{X}_{\alpha(\check{f}^{m_{l+1}}(\check{z}))}$ project onto \mathcal{A} we have that

$$|p_1(\check{f}^{m_l}(\check{z})) - p_1(\check{f}^{m_{l+1}}(\check{z}))| \leq M_{\mathcal{A}}^0 + M_{\mathcal{A}}^1.$$

We deduce the following lemma.

Lemma 4.5. *Let $l', l'' \in \{1, \dots, s-2\}$ with $l' < l''$. Suppose that $\check{X}_{\alpha(\check{f}^{m_{l'}}(\check{z}))}$ and $\check{X}_{\alpha(\check{f}^{m_{l''}}(\check{z}))}$ project onto \mathcal{A}' . If*

$$|p_1(\check{f}^{m_{l'}}(\check{z})) - p_1(\check{f}^{m_{l''}}(\check{z}))| \geq (6r' + 1)(M_{\mathcal{A}}^0 + M_{\mathcal{A}}^1),$$

then

- (a) there exist at least three points $f^{m_{l_k}}(\tilde{\pi}(\check{z}))$ that belong to the same X_i , or
- (b) there exists $l \in \{l', \dots, l''\}$ such that $\check{X}_{\alpha(\check{f}^{m_l}(\check{z}))}$ projects onto $\mathcal{A}_N \cup \mathcal{A}_S$.

Proof. Suppose that Assertion (b) does not hold, that is (by (1)) the points $\check{f}^{m_{l'}}(\check{z}), \check{f}^{m_{l'+1}}(\check{z}), \dots, \check{f}^{m_{l''}}(\check{z})$ are contained in $\check{\mathcal{A}}'$. If

$$|p_1(\check{f}^{m_{l'}}(\check{z})) - p_1(\check{f}^{m_{l''}}(\check{z}))| \geq (6r' + 1)(M_{\mathcal{A}}^0 + M_{\mathcal{A}}^1)$$

then by above Property (ii), $l'' - l' \geq 6r' + 1$ and so, by above Property (i), there exist at least $3r'$ sets $\check{X}_{\alpha(\check{f}^{m_{l_k}}(\check{z}))}$, $l' < l_k < l''$, that do not project on $\mathcal{A}' \cap V$. This implies that Assertion (a) holds, completing the proof of the lemma. ■

Let us define

$$M^0 = (6r' + 1)(M_{\mathcal{A}}^0 + M_{\mathcal{A}}^1) \quad \text{and} \quad M^1 = \text{diam}(V_{\check{K}}),$$

where $V_{\check{K}}$ is the neighborhood of \check{K} provided by Lemma 4.3.

End of the proof of Theorem A. By Lemma 4.3, we deduce that for every integer $t \geq 1$, there exist a point $\check{z} \in \check{\mathcal{A}}'$ and different integers i_1, \dots, i_t such that for every $j \in \{1, \dots, t\}$, $\check{f}^{i_j}(\check{z}) \in \check{\mathcal{A}}'$ and one has

$$|p_1(\check{f}^{i_j}(\check{z})) - p_1(\check{f}^{i_{j+1}}(\check{z}))| \geq M^0 + 2M_{\mathcal{A}}^1.$$

Considering the sequence $m_0 < m_1 < \dots < m_s$ associated to \check{z} , we have

$$|p_1(\check{f}^{m_{l'}}(\check{z})) - p_1(\check{f}^{m_{l''}}(\check{z}))| \geq M^0.$$

Hence, if Case (a) from Lemma 4.5 holds for some $j \in \{1, \dots, t\}$, then there exist at least three points $f^{m_{l_k}}(\tilde{\pi}(\check{z}))$ that belong to the same X_i . Otherwise, there exists $l' < l^* < l''$ such that, $\check{X}_{\alpha(\check{f}^{m_{l^*}}(\check{z}))}$ projects onto $\mathcal{A}_N \cup \mathcal{A}_S$. Hence if $t \geq 3 \max\{r_N, r_S\}$, then there exist at least $3 \max\{r_N, r_S\}$ sets $\check{X}_{\alpha(\check{f}^{m_l}(\check{z}))}$ project onto $\mathcal{A}_N \cup \mathcal{A}_S$, and so there exist at least three points $f^{m_{l_k}}(\tilde{\pi}(\check{z}))$ that belong to the same X_i . Therefore, by Lemma 4.1, it follows that Case (1) of Theorem A holds. This completes the proof of Theorem A. ■

5 Examples

Given a measure-preserving irrotational homeomorphism f of the open annulus \mathbb{A} . Further assume that the connected components of the set of fixed points of f are all compact. Suppose that the set of fixed points of the irrotational lift, \check{f} , of f to $\check{\mathbb{A}}$ projects into an open topological disk of \mathbb{A} . It follows from Theorem A that for every compact set K of \mathbb{A} , there exists a real constant $M > 0$ such that, for every $\check{z} \in \check{\mathbb{A}}$ and every integer $n \geq 1$ such that \check{z} and $\check{f}^n(\check{z})$ belong to $\check{\pi}^{-1}(K)$, one has

$$|p_1(\check{f}^n(\check{z})) - p_1(\check{z})| \leq M.$$

We will describe (in the following proposition) an example to show that in general one may not expect this bound to be independent of the compact set.

Proposition 5.1. *There exists an irrotational homeomorphism f_{bound} of \mathbb{A} which preserves a Borel probability measure of full support satisfying:*

- (1) *the set of fixed points of the irrotational lift \check{f}_{bound} of f_{bound} projects into an open topological disk of \mathbb{A} ;*
- (2) *the connected components of the set of fixed points of f_{bound} are all compact;*
- (3) *for every real number $\eta > 0$ and every integer $j \geq 1$ there exist a point $\check{z} \in \check{\mathbb{A}}$ and an integer $n \geq 1$ such that*

$$\check{z} \in [0, \eta] \times [j, j+1] \quad \text{and} \quad \check{f}_{\text{bound}}^n(\check{z}) \in [j, j+\eta] \times [j, j+1].$$

- (4) *the homeomorphism f_{bound} of \mathbb{A} extends continuously to the semi-closed annulus $\mathbb{A}_{+\infty} := \mathbb{T}^1 \times (-\infty, +\infty]$ as the identity on the circle $\mathbb{T}^1 \times \{+\infty\}$.*

The example from previous proposition will permit us to describe another example showing that the hypothesis “the connected components of the set of fixed points of f are all compact” is essential in the conclusion of Theorem A. In the following example none of Cases of Theorem A hold.

Proposition 5.2. *There is an irrotational homeomorphism f_{none} of \mathbb{A} which preserves a Borel probability measure of full support satisfying:*

- (1) *the set of fixed points of the irrotational lift \check{f}_{none} of f_{none} projects into an open topological disk of \mathbb{A} ;*
- (2) *there exists a compact set K_0 of \mathbb{A} such that for every real number $M > 0$, there exist a point $\check{z} \in \check{\mathbb{A}}$ and an integer $n \geq 1$ such that, \check{z} and $\check{f}^n(\check{z})$ belong to $\check{\pi}^{-1}(K_0)$, and*

$$|p_1(\check{f}_{\text{none}}^n(\check{z})) - p_1(\check{z})| \geq M.$$

To obtain the example from Proposition 5.1, it suffices to prove the following proposition.

Proposition 5.3. *Let x_0, x'_0 and x_1, x'_1 be four points in \mathbb{T}^1 and let $\epsilon > 0$ be a real number. Then there exists a real number $\delta > 0$ such that, given two irrotational diffeomorphisms $g_0, g_1 : \mathbb{T}^1 \rightarrow \mathbb{T}^1$ which are different to the identity, x_i and x'_i are fixed points of g_i , $i \in \{0, 1\}$, and are δ -close to the identity in the C^1 -topology, and an integer $j \geq 1$ there is an area-preserving irrotational homeomorphism $f : \mathbb{T}^1 \times [0, 1] \rightarrow \mathbb{T}^1 \times [0, 1]$ which is isotopic to the identity and satisfies:*

- (a) *f coincides with g_0 (resp. g_1) on the boundary component $\mathbb{T}^1 \times \{0\}$ (resp. $\mathbb{T}^1 \times \{1\}$);*
- (b-1) *there exists a path that joins $\mathbb{T}^1 \times \{0\}$ to $\mathbb{T}^1 \times \{1\}$, it is contained in the interior of $\mathbb{T}^1 \times [0, 1]$, but the endpoints, and it does not intersect the set of fixed points of f ;*
- (b-2) *there exists a loop in the interior of $\mathbb{T}^1 \times [0, 1]$ which is not homotopic to zero, and it does not intersect the set of fixed points of f ;*
- (c) *For every real number $\eta > 0$ there exist a point $\tilde{z} \in \mathbb{R} \times [0, 1]$ and an integer $n \geq 1$ such that*

$$\tilde{z} \in [0, \eta] \times [0, 1] \quad \text{and} \quad \tilde{f}^n(\tilde{z}) \in [j, j + \eta] \times [0, 1].$$

- (d) *f is ϵ -close to the identity in the C^0 -topology.*

This proposition will be proved at the end of this section. In what follows, we will prove Propositions 5.1 and 5.2 assuming Proposition 5.3.

5.1 Proof of Propositions 5.1 and 5.2

Proof of Proposition 5.1. For every $n \in \mathbb{Z}$, let $z_n := (0, n)$ and $z'_n := (1/2, n)$ be points in \mathbb{A} . Let us fix a sequence of positive real numbers $(\epsilon_n)_{n \in \mathbb{Z}}$ which converges to 0 as n to $+\infty$ and consider the sequence of positive real numbers $(\delta_n)_{n \in \mathbb{Z}}$ such that $\delta_n < \epsilon_n$ given by Proposition 5.3. Let us consider a sequence $(g_n)_{n \in \mathbb{Z}}$ of diffeomorphisms of the circle \mathbb{T}^1 as in Proposition 5.3 (g_n fixes only 0 and 1/2) which converges to the identity as n to $+\infty$ and a sequence of positive integers $(j_n)_{n \in \mathbb{Z}}$ which goes to $+\infty$ as n to $+\infty$. For every integer n we can define an area-preserving irrotational homeomorphism f_n on the closed annulus $A_n = \mathbb{T}^1 \times [n, n + 1] \subset \mathbb{A}$ which satisfies the properties formulated in Proposition 5.3. Let us define the homeomorphism f_{bound} of the open annulus \mathbb{A} which coincides with f_n on $A_n \subset \mathbb{A}$. We note that this homeomorphism preserves a Borel probability measure of full support. Moreover, Properties (1) and (2) in Proposition 5.1 follows of Properties (b-1) and (b-2) in Proposition 5.3 respectively. Moreover, Properties (3) and (4) in Proposition 5.1 follows of Property (c) in Proposition 5.3 and Property (d) in Proposition 5.3 and the chosen of the sequence $(\epsilon_n)_{n \in \mathbb{Z}}$ respectively. This completes the proof of the proposition. ■

Proof of Propositions 5.2. Let us define the following equivalence relation on the semi-closed annulus $\mathbb{A}_{+\infty} := \mathbb{T}^1 \times (-\infty, +\infty]$.

$$(x, y) \sim (x', y') \text{ if and only if } \begin{cases} x = x' \text{ and } y = y'; \\ y = y' = +\infty, x \in [0, 1/4] \text{ and } x' = 1 - x. \end{cases}$$

Let $\mathbb{A}'_{+\infty} := \mathbb{A}_{+\infty} / \sim$ be the quotient space of $\mathbb{A}_{+\infty}$. For $(x, y) \in \mathbb{A}_{+\infty}$, we write $[(x, y)]$ the equivalence class of (x, y) . Now, it is easy to check that $\mathbb{A}'_{+\infty}$ is homeomorphic to $\mathbb{A}_{+\infty}$ and let $\varphi : \mathbb{A}'_{+\infty} \rightarrow \mathbb{A}_{+\infty}$ be such a homeomorphism which acts as the identity on a neighborhood of the set $\{(1/2, y) : y \in \mathbb{R} \cup \{+\infty\}\}$. Now, as f_{bound} is the identity on the circle $\mathbb{T}^1 \times \{+\infty\}$ (Property (4) in Proposition 5.1), it induces a homeomorphism f'_{none} on $\mathbb{A}'_{+\infty}$ which acts as the identity on the segment $L_{+\infty} := \{[(x, +\infty)] : x \in [0, 1/4]\}$. We denote by f_{none} the restriction to \mathbb{A} of the homeomorphism $\varphi f'_{none} \varphi^{-1}$ defined on the semi-closed annulus $\mathbb{A}_{+\infty}$. We note that f_{none} is isotopic to the identity of \mathbb{A} . Let K_0 be a closed topological disk in \mathbb{A} that contains $\varphi([(0, +\infty)]) \in \varphi(L_{+\infty})$ in its interior. We note that there exist an integer n_0 and a real number $\eta_0 > 0$ such that

$$\varphi(\{[(x, y)] : (x, y) \in [n_0, +\infty] \times [-\eta_0, \eta_0]\}) \subset K_0.$$

(see Figure 5).

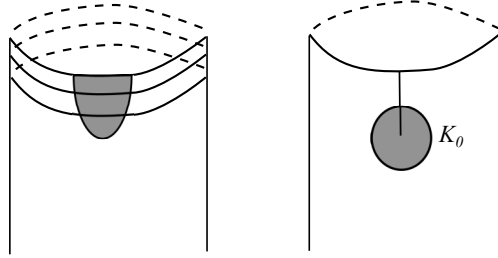

Figure 5: The set K_0 .

Hence Property (2) in Proposition 5.2 follows of Property (3) in Proposition 5.1. Moreover, as φ acts as the identity on a neighborhood of $\{1/2\} \times \mathbb{R}$, Property (1) in Proposition 5.2 follows of Property (1) in Proposition 5.1. This completes the proof of Proposition 5.2. \blacksquare

5.2 Proof of Proposition 5.3

We use the following lemma (see [KT3]). It can be obtained by a straightforward adaptation of the proof of Proposition 2.2 from [BCW].

Lemma 5.4. *For every real number $\epsilon > 0$ there exists a real number $\delta > 0$ such that, if $g : \mathbb{T}^1 \rightarrow \mathbb{T}^1$ is a diffeomorphism of the circle which is δ -close to the identity in the C^1 -topology, then there exists an area-preserving diffeomorphism $f : \mathbb{T}^1 \times [0, 1] \rightarrow \mathbb{T}^1 \times [0, 1]$ of the closed annulus which is ϵ -close to the identity in the C^1 -topology satisfying $f(x, 1) = (g(x), 1)$ and $f(x, 0) = (x, 0)$ for every $x \in \mathbb{T}^1$.*

We deduce the following corollary.

Corollary 5.5. *For every real number $\epsilon > 0$ there exists a real number $\delta > 0$ such that, if $g : \mathbb{S}^1 \rightarrow \mathbb{S}^1$ is a diffeomorphism of the unit circle of the plane which is δ -close to the identity in the C^1 -topology, then there exists an area-preserving homeomorphism $f : \mathbb{D} \rightarrow \mathbb{D}$ of the closed unit disk which is ϵ -close to the identity in the C^1 -topology satisfying $f|_{\mathbb{S}^1} = g$. Moreover, if z_0 and z_1 are not fixed points of g , then there exists a path in the interior of \mathbb{D} , but the endpoints, that joins z_0 to z_1 .*

Proof. If $g : \mathbb{S}^1 \rightarrow \mathbb{S}^1$ is a diffeomorphism which is δ -close to the identity, then applying the above lemma one can conclude that there exists an area-preserving diffeomorphism f' as the above lemma. Collapsing the boundary component $\mathbb{T}^1 \times \{0\}$ to a point, we obtain an area-preserving homeomorphism f of the closed unit disk \mathbb{D} of \mathbb{R}^2 which is ϵ -close to the identity such that $f|_{\partial\mathbb{D}} = g$. ■

Proof of Proposition 5.3. Our proof is an adaptation of the proof of the last claim from [KT3]. Let consider a topological flow $(\phi_t)_{t \in \mathbb{R}}$ on the closed annulus lifting to a flow $(\check{\phi}_t)_{t \in \mathbb{R}}$ of $\mathbb{R} \times [0, 1]$ such that:

- ϕ_t is area-preserving for every $t \in \mathbb{R}$;
- the square $\check{D}_0 := (0, 1/2) \times (0, 1)$ is $\check{\phi}_t$ -invariant for every $t \in \mathbb{R}$;
- there are finitely many singularities and no essential closed “connections”;
- there are not singularities on the boundary of \check{D}_0 but the vertices.

We note that by construction for each $t \in \mathbb{R}$ there is a circle $\check{\phi}_t$ -invariant, close enough of the boundary of \check{D}_0 such that the restriction of $\check{\phi}_t$ on this circle is transitive. Given an integer $j \geq 1$, let us consider the homeomorphism $H : \mathbb{R} \times [0, 1] \rightarrow \mathbb{R} \times [0, 1]$ defined as

$$H(\check{x}, y) := (\check{x}, y) + ((j+1)\sin(2\pi y), 0).$$

We write $T : (\check{x}, y) \mapsto (\check{x}+1, y)$. Note that $TH = HT$ and that the projection of the topological disk $\check{D} = H(\check{D}_0)$ onto the first coordinate has diameter greater than j . For every $t \in \mathbb{R}$, consider

$$\check{f}_t := H\check{\phi}_tH^{-1}.$$

It is easy to check that $T\check{f}_t = \check{f}_tT$, $\check{f}_t(\check{D}) = \check{D}$, and that for every integer n , $\check{f}_t^n = H\check{\phi}_t^nH^{-1}$. Moreover given a real number $\eta > 0$, both sets

$$H^{-1}([0, \eta] \times [0, 1]) \cap \check{D}_0 \quad \text{and} \quad H^{-1}([j, j+\eta] \times [0, 1]) \cap \check{D}_0$$

are the union of two disjoint bands which separate $(0, 1/2) \times \{0\}$ and $(0, 1/2) \times \{1\}$. Therefore for every $t \in \mathbb{R}$ using the above ϕ_t -invariant circle we can find a point \tilde{z} and an integer $n \geq 1$ such that

$$\tilde{z} \in [0, \eta] \times [0, 1] \quad \text{and} \quad \tilde{f}_t^n(\tilde{z}) \in [j, j + \eta] \times [0, 1].$$

For $i \in \{-1, 0, 1\}$, let $A_i = \mathbb{T}^1 \times [i, i+1]$. Given x_0, x'_0, x_1 and x'_1 four points in \mathbb{T}^1 let $z_{-1} = (x_0, -1)$, $z'_{-1} = (x'_0, -1)$; $z_0 = (0, 0)$, $z'_0 = (1/2, 0)$; $z_1 = (0, 1)$, $z'_1 = (1/2, 1)$; $z_2 = (x_1, 2)$, $z'_2 = (x'_1, 2)$. For each $i \in \{-1, 1\}$ consider two pairwise segments α_i and α'_i joining z_i to z_{i+1} and z'_i and z'_{i+1} respectively. These two segments divide the interior of the closed annulus A_i in two open topological disks D_i and D'_i whose closure are closed disks. Given a real number $\epsilon > 0$, by Corollary 5.5 applied on each closed disk $\overline{D_i}, \overline{D'_i}$, $i \in \{-1, 1\}$ we obtain a real number $0 < \delta < \epsilon$. Define f on A_0 as $f = f_t$, where t is chosen small enough so as to guarantee that f_t is δ -close to the identity in the C^1 -topology. For each $i \in \{-1, 1\}$ let us choose two diffeomorphisms $g_{\alpha_i} : \alpha_i \rightarrow \alpha_i$ and $g'_{\alpha_i} : \alpha'_i \rightarrow \alpha'_i$ without fixed point but the endpoints close enough to the identity such that the diffeomorphisms induced on ∂D_i and $\partial D'_i$ by $g_0, g_1, f, g_{\alpha_i}$ and g'_{α_i} (and their inverses) are δ -close to the identity. We can apply Corollary 5.5 on each disk $\overline{D_i}$ and $\overline{D'_i}$ to obtain an area-preserving homeomorphism f_i and f'_i of $\overline{D_i}$ and $\overline{D'_i}$ respectively which are ϵ -close to the identity. We consider now the homeomorphism of $\mathbb{T}^1 \times [-1, 2]$ which coincides with f on A_0 and with f_i and f'_i on $\overline{D_i}$ and $\overline{D'_i}$, $i \in \{-1, 1\}$, respectively. Rescaling the annulus vertically we obtain a homeomorphism which satisfies the conditions of Proposition 5.3. This completes the proof of the proposition. \blacksquare
